This specification is related to:

OASIS Reference Model for Service Oriented Architecture

Abstract:

This document specifies the OASIS Reference Architecture Foundation for Service Oriented Architecture (SOA-RAF). It follows from the concepts and relationships defined in the OASIS Reference Model for Service Oriented Architecture. While it remains abstract in nature, the current document describes the foundation upon which specific SOA concrete architectures can be built.

The focus of the SOA-RAF is on an approach to integrating business with the information technology needed to support it. These issues are always present but are all the more important when business integration involves crossing ownership boundaries.

The SOA-RAF follows the recommended practice of describing architecture in terms of models, views, and viewpoints, as prescribed in the ANSI/IEEE 1471-2000 (now ISO/IEC 42010-2007)

Standard. The SOA-RAF is of value to Enterprise Architects, Business and IT Architects as well as CIOs and other senior executives involved in strategic business and IT planning.

The SOA-RAF has three main views: the *Participation in a SOA Ecosystem* view which focuses on the way that participants are part of a Service Oriented Architecture ecosystem; the *Realization of a SOA Ecosystem* view which addresses the requirements for constructing a SOAbased system in a SOA ecosystem; and the *Ownership in a SOA Ecosystem* view which focuses on what is meant to own a SOA-based system.

Status:

This document was last revised or approved by the OASIS Service Oriented Architecture Reference Model TC on the above date. The level of approval is also listed above. Check the "Latest version" location noted above for possible later revisions of this document.

Technical Committee members should send comments on this specification to the Technical Committee's email list. Others should send comments to the Technical Committee by using the "Send A Comment" button on the Technical Committee's web page at http://www.oasisopen.org/committees/soa-rm/.

For information on whether any patents have been disclosed that may be essential to implementing this specification, and any offers of patent licensing terms, please refer to the Intellectual Property Rights section of the Technical Committee web page (http://www.oasis-open.org/committees/soa-rm/ipr.php).

1 1 Introduction

11

12

13

14

2 Service Oriented Architecture (SOA) is an architectural paradigm that has gained significant attention

within the information technology (IT) and business communities. The SOA ecosystem described in this
 document occupies the area between business and IT. It is neither wholly IT nor wholly business, but is of
 both worlds. Neither business nor IT completely own, govern and manage this SOA ecosystem. Both sets
 of concerns must be accommodated for the SOA ecosystem to fulfill its purposes.¹

- The OASIS Reference Model for SOA [SOA-RM] provides a common language for understanding the
 important features of SOA but does not address the issues involved in constructing, using or owning a
 SOA-based system. This document focuses on these aspects of SOA.
- 10 The intended audiences of this document and expected benefits to be realized include non-exhaustively:
 - Enterprise Architects will gain a better understanding when planning and designing enterprise systems of the principles that underlie Service Oriented Architecture;
 - Standards Architects and Analysts will be able to better position specific specifications in relation to each other in order to support the goals of SOA;
- Decision Makers will be better informed as to the technology and resource implications of
 commissioning and living with a SOA-based system; in particular, the implications following from
 multiple ownership domains; and
- Users/Developers will gain a better understanding of what is involved in participating in a SOAbased system.

1.1 Context for Reference Architecture for SOA

21 1.1.1 What is a Reference Architecture?

A reference architecture models the abstract architectural elements in the domain of interest independent of the technologies, protocols, and products that are used to implement a specific solution for the domain.

24 It differs from a reference model in that a reference model describes the important concepts and

relationships in the domain focusing on what distinguishes the elements of the domain; a reference

architecture elaborates further on the model to show a more complete picture that includes showing what

is involved in realizing the modeled entities, while staying independent of any particular solution butinstead applies to a class of solutions.

29 It is possible to define reference architectures at many levels of detail or abstraction, and for many

30 different purposes. A reference architecture is not a concrete architecture; i.e., depending on the

- requirements being addressed by the reference architecture, it generally will not completely specify all the
- technologies, components and their relationships in sufficient detail to enable direct implementation.

¹ By *business* we refer to any activity that people are engaged in. We do not restrict the scope of SOA ecosystems to commercial applications.

1.1.2 What is this Reference Architecture?

34 There is a continuum of architectures, from the most abstract to the most detailed. This Reference

Architecture is an abstract realization of SOA, focusing on the elements and their relationships needed to enable SOA-based systems to be used, realized and owned while avoiding reliance on specific concrete

36 enable SOA-based systems to be used, realized and owned while avoiding reliance on specific concrete 37 technologies. This positions the work at the more abstract end of the continuum, and constitutes what is

described in [TOGAF v9] as a "foundation architecture". It is nonetheless a *reference* architecture as it

remains solution-independent and is therefore characterized as a *Reference Architecture Foundation*

- 40 because it takes a first principles approach to architectural modeling of SOA-based systems.
- 41 While requirements are addressed more fully in Section 0, the SOA-RAF makes key assumptions that 42 SOA-based systems involve:
 - Use of resources that are distributed across ownership boundaries;
 - people and systems interacting with each other, also across ownership boundaries;
 - security, management and governance that are similarly distributed across ownership boundaries; and
- interaction between people and systems that is primarily through the exchange of messages with
 reliability that is appropriate for the intended uses and purposes.

Even in apparently homogenous structures, such as within a single organization, different groups and
 departments nonetheless often have ownership boundaries between them. This reflects organizational
 reality as well as the real motivations and desires of the people running those organizations.

- 52 Such an environment as described above is an *ecosystem* and, specifically in the context of SOA-based 53 systems, is a **SOA ecosystem**. This concept of an ecosystem perspective of SOA is elaborated further in 54 Section 1.2.
- 55 This SOA-RAF shows how Service Oriented Architecture fits into the life of users and stakeholders, how
- 56 SOA-based systems may be realized effectively, and what is involved in owning and managing them.
- 57 This serves two purposes: to ensure that SOA-based systems take account of the specific constraints of
- a SOA ecosystem, and to allow the audience to focus on the high-level issues without becoming over-
- 59 burdened with details of a particular implementation technology.

60 1.1.3 Relationship to the OASIS Reference Model for SOA

- 61 The OASIS Reference Model for Service Oriented Architecture identifies the key characteristics of SOA
- 62 and defines many of the important concepts needed to understand what SOA is and what makes it

important. The Reference Architecture Foundation takes the Reference Model as its starting point, in
 particular the vocabulary and definition of important terms and concepts.

- 65 The SOA-RAF goes further in that it shows how SOA-based systems can be realized albeit in an
- abstract way. As noted above, SOA-based systems are better thought of as dynamic systems rather than
- stand-alone software products. Consequently, how they are used and managed is at least as important
 architecturally as how they are constructed.

69 **1.1.4 Relationship to other Reference Architectures**

- 70 Other SOA reference architectures have emerged in the industry, both from the analyst community and
- the vendor/solution provider community. Some of these reference architectures are quite abstract in
- relation to specific implementation technologies, while others are based on a solution or technology stack.
- 73 Still others use middleware technology such as an Enterprise Service Bus (ESB) as their architectural
- 74 foundation.

43

44

45

46

- As with the Reference Model, this Reference Architecture is primarily focused on large-scale distributed
- 76 IT systems where the participants may be legally separate entities. It is quite possible for many aspects of 77 this Reference Architecture to be realized on quite different platforms.
- 78 In addition, this Reference Architecture Foundation, as the title illustrates, is intended to provide
- foundational models on which to build other reference architectures and eventual concrete architectures.
- 80 The relationship to several other industry reference architectures for SOA and related SOA open
- 81 standards is described in Appendix E.

1.1.5 Expectations set by this Reference Architecture Foundation

83 This Reference Architecture Foundation is not a complete blueprint for realizing SOA-based systems. Nor

is it a technology map identifying all the technologies needed to realize SOA-based systems. It does

identify many of the key aspects and components that will be present in any well designed SOA-based

86 system. In order to actually use, construct and manage SOA-based systems, many additional design

87 decisions and technology choices will need to be made.

1.2 Service Oriented Architecture – An Ecosystems Perspective

90 Many systems cannot be completely understood by a simple decomposition into parts and subsystems –

91 in particular when many autonomous parts of the system are governing interactions. We need also to 92 understand the context within which the system functions and the participants involved in making it

93 function. This is the *ecosystem*. For example, a biological ecosystem is a self-sustaining and dynamic

94 association of plants, animals, and the physical environment in which they live. Understanding an

95 ecosystem often requires a holistic perspective that considers the relationships between the elements of

96 the system and their environment at least as important as the individual parts of the system.

97 This Reference Architecture Foundation views the SOA architectural paradigm from an ecosystems

98 perspective: whereas a system will be a capability developed to fulfill a defined set of needs, a SOA

99 ecosystem is a space in which people, processes and machines act together to deliver those capabilities

100 as services.

101 Viewed as whole, a SOA ecosystem is a network of discrete processes and machines that, together with

- a community of people, creates, uses, and governs specific services as well as external suppliers of
 resources required by those services.
- In a SOA ecosystem there may not be any single person or organization that is really "in control" or "in
 charge" of the whole although there are identifiable stakeholders who have influence within the
 community and control over aspects of the overall system.
- 107 The three key principles that inform our approach to a SOA ecosystem are:
- a SOA is a paradigm for *exchange of value* between independently acting *participants*;
- participants (and stakeholders in general) have legitimate claims to *ownership* of resources that are made available via the SOA; and
- the behavior and performance of the participants are subject to *rules of engagement* which are captured in a series of policies and contracts.

113 **1.3 Viewpoints, Views and Models**

114 1.3.1 ANSI/IEEE 1471-2000::ISO/IEC 42010-2007

- 115 1. The SOA-RAF uses and follows the IEEE "Recommended Practice for Architectural Description 116 of Software-Intensive Systems" **[ANSI/IEEE 1471] and [ISO/IEC 42010]**. An architectural
- 117 description conforming to this standard must include the following six (6) elements:
- 118 2. Architectural description identification, version, and overview information

- 119 Identification of the system stakeholders and their concerns judged to be relevant to the 120 architecture
- 121 4. Specifications of each viewpoint that has been selected to organize the representation of the 122 architecture and the rationale for those selections
- 123 5. One or more architectural views
- 6. A record of all known inconsistencies among the architectural description's required constituents 124
- 7. A rationale for selection of the architecture (in particular, showing how the architecture supports 125 126 the identified stakeholders' concerns).
- The standard defines the following terms²: 127

128 Architecture

129 The fundamental organization of a system embodied in its components, their relationships to each other, and to the environment, and the principles guiding its design and evolution. 130

131 **Architectural Description**

A collection of products that document the architecture.

133 System

132

A collection of components organized to accomplish a specific function or set of functions. 134

135 System Stakeholder

- 136 A system stakeholder is an individual, team, or organization (or classes thereof) with interests in, 137 or concerns relative to, a system.
- 138 A stakeholder's concern should not be confused with either a need or a formal requirement. A concern,
- 139 as understood here, is an area or topic of interest. Within that concern, system stakeholders may have 140 many different requirements. In other words, something that is of interest or importance is not the same
- 141 as something that is obligatory or of necessity [TOGAF v9].
- When describing architectures, it is important to identify stakeholder concerns and associate them with 142
- viewpoints to insure that those concerns are addressed in some manner by the models that comprise the 143 views on the architecture. The standard defines views and viewpoints as follows:
- 144
- 145 View
- 146 A representation of the whole system from the perspective of a related set of concerns.

147 Viewpoint

- 148 A specification of the conventions for constructing and using a view. A pattern or template from which to develop individual views by establishing the purposes and audience for a view and the 149 150 techniques for its creation and analysis.
- 151 In other words, a view is what the stakeholders see whereas the viewpoint defines the perspective from 152 which the view is taken and the methods for, and constraints upon, modeling that view.
- 153 It is important to note that viewpoints are independent of a particular system (or solutions). In this way,
- the architect can select a set of candidate viewpoints first, or create new viewpoints, and then use those 154
- viewpoints to construct specific views that will be used to organize the architectural description. A view, 155
- 156 on the other hand, is specific to a particular system. Therefore, the practice of creating an architectural

² See http://www.iso-architecture.org/ieee-1471/conceptual-framework.html for a diagram of the standard's **Conceptual Framework**

- 157 description involves first selecting the viewpoints and then using those viewpoints to construct specific
- 158 views for a particular system or subsystem. Note that the standard requires that each view corresponds to
- exactly one viewpoint. This helps maintain consistency among architectural views which is a normative
- 160 requirement of the standard.
- 161 A view is comprised of one or more architectural models, where model is defined as:
- 162 **Model**
- 163 An abstraction or representation of some aspect of a thing (in this case, a system)

164 All architectural models used in a particular view are developed using the methods established by the

architectural viewpoint associated with that view. An architectural model may participate in more than one view but a view must conform to a single viewpoint.

167 **1.3.2 UML Modeling Notation**

168 An open standard modeling language is used to help visualize structural and behavioral architectural

- 169 concepts. Although many architecture description languages exist, we have adopted the Unified
- 170 Modeling Language[™] 2 (UML[®] 2) [UML 2] as the main viewpoint modeling language. Normative UML is
- 171 used unless otherwise stated but it should be noted that it can only partially describe the concepts in each
- model it is important to read the text in order to gain a more complete understanding of the concepts
- 173 being described in each section..
- Appendix The Unified Modeling Language, UML introduces the UML notation that is used in thisdocument.

176 **1.4 SOA-RAF Viewpoints**

177 The RAF uses three views that conform to three viewpoints: Participation in a SOA Ecosystem,

178 Realization of a SOA Ecosystem, and Ownership in a SOA Ecosystem. There is a one-to-one

179 correspondence between viewpoints and views (see Table 1).

	Viewpoint			
Viewpoint Element	Participation in a SOA Ecosystem	Realization of a SOA Ecosystem	Ownership in a SOA Ecosystem	
Main concepts covered	Captures what is meant for people to participate in a SOA ecosystem.	Captures what is meant to realize a SOA-based system in a SOA ecosystem.	Captures what is meant to own a SOA-based system in a SOA ecosystem	
Stakeholders addressed	All participants in the SOA ecosystem	Those involved in the design, development and deployment of SOA-based systems	Those involved in governing, managing, securing, and testing SOA-based systems	
Concerns addressed Understanding ecosystem constraints and contexts in which business can be conducted predictably and effectively.		Effective construction of SOA-based systems.	Processes to ensure governance, management, security, and testing of SOA- based systems.	
Modeling Techniques used	UML class diagrams	UML class, sequence, component, activity, communication, and composite structure diagrams	UML class and communication diagrams	

180 Table 1 - Viewpoint specifications for the OASIS Reference Architecture Foundation for SOA

181 **1.4.1 Participation in a SOA Ecosystem Viewpoint**

- 182 This viewpoint captures a SOA ecosystem as an environment for people to conduct their business. We
- do not limit the applicability of such an ecosystem to commercial and enterprise systems. We use the
- 184 term business to include any transactional activity between multiple users.
- 185 All stakeholders in the ecosystem have concerns addressed by this viewpoint. The primary concern for
- 186 people is to ensure that they can conduct their business effectively and safely in accordance with the
- 187 SOA paradigm. The primary concern of decision makers is the relationships between people and
- organizations using systems for which they, as decision makers, are responsible but which they may not
- 189 entirely own, and for which they may not own all of the components of the system.
- 190 Given SOA's value in allowing people to access, manage and provide services across ownership
- boundaries, we must explicitly identify those boundaries and the implications of crossing them.

192 **1.4.2 Realization of a SOA Ecosystem Viewpoint**

- 193 This viewpoint focuses on the infrastructure elements that are needed to support the construction of SOA-
- based systems. From this viewpoint, we are concerned with the application of well-understood
- 195 technologies available to system architects to realize the SOA vision of managing systems and services that cross ownership boundaries
- 196 that cross ownership boundaries.
- The stakeholders are essentially anyone involved in designing, constructing and deploying a SOA-basedsystem.

199 **1.4.3 Ownership in a SOA Ecosystem Viewpoint**

- 200 This viewpoint addresses the concerns involved in owning and managing SOA-based systems within the
- SOA ecosystem. Many of these concerns are not easily addressed by automation; instead, they often
- 202 involve people-oriented processes such as governance bodies.
- 203 Owning a SOA-based system implies being able to manage an evolving system. It involves playing an 204 active role in a wider ecosystem. This viewpoint is concerned with how systems are managed effectively,
- how decisions are made and promulgated to the required end points; how to ensure that people may use
- the system effectively; and how the system can be protected against, and recover from consequences of,
- 207 malicious intent.

208 **1.5 Terminology**

- 209 The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD
- NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in **[RFC2119]**.
- 212 References are surrounded with [square brackets and are in bold text].
- 213 The terms "SOA-RAF", "this Reference Architecture" and "Reference Architecture Foundation" refer to
- this document, while "the Reference Model" refers to the OASIS Reference Model for Service Oriented
- 215 Architecture". [SOA-RM].

216 **1.5.1 Usage of Terms**

- 217 Certain terms used in this document to denote concepts with formal definitions and are used with specific
- 218 meanings. Where reference is made to a formally defined concept and the prescribed meaning is
- 219 intended, we use a **bold font**. The first time these terms are used, they are also hyperlinked to their
- definition in the body of the text. Where a more colloquial or informal meaning is intended, these words
- are used without special emphasis.

284 **2 Architectural Goals and Principles**

This section identifies the goals of this Reference Architecture Foundation and the architectural principlesthat underpin it.

287 2.1 Goals and Critical Success Factors of the Reference 288 Architecture Foundation

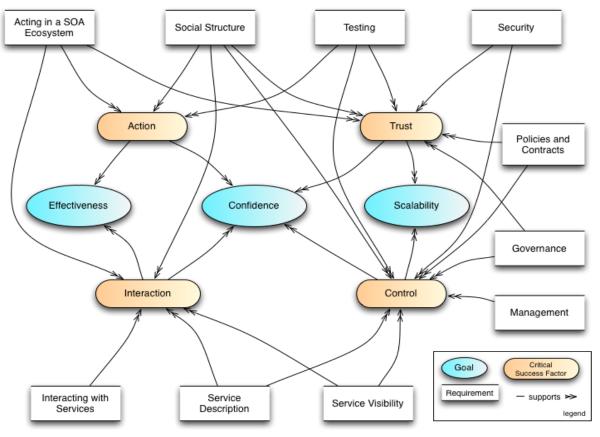

289 There are three principal goals:

292

293

299

- to show how SOA-based systems can effectively bring participants with needs ('consumers') to
 interact with participants offering appropriate capabilities as services ('producers');
 - 2. for participants to have a clearly understood level of confidence as they interact using SOA-based systems; and
- 3. for SOA-based systems to be scaled for small or large systems as needed.
- 295 There are four factors critical to the achievement of these goals:
- 296 1. Action: an account of participants' action within the ecosystem;
- Trust: an account of how participants' internal perceptions of the reliability of others guide their
 behavior (i.e., the trust that participants may or may not have in others)
 - 3. Interaction: an account of how participants can interact with each other; and
- 300
 4. Control: an account of how the management and governance of the entire SOA ecosystem can be arranged.

302

303 Figure 1 - Critical Factors Analysis of the Reference Architecture

- Figure 1 represents a Critical Factors Analysis (CFA) diagram demonstrating the relationship between the primary goals of this reference architecture, critical factors that determine the success of the architecture and individual elements that need to be modeled.
- 307 A CFA is a structured way of arriving at the requirements for a project, especially the quality attribute
- 308 (non-functional) requirements; as such, it forms a natural complement to other requirements capture
- 309 techniques such as use-case analysis, which are oriented more toward functional requirements capture.
- 310 The CFA requirement technique and the diagram notation are summarized in Appendix B.

311 2.1.1 Goals

312 2.1.1.1 Effectiveness

A primary purpose of the SOA-RAF is to show how SOA-based systems ensure that participants can use the facilities of the system to meet their needs. This does not imply that every need has a SOA solution, but for those needs that can benefit, we look at what is needed to use the SOA paradigm effectively.

- 316 The key factors that govern effectiveness from a participant's perspective are actions undertaken-
- 317 especially across ownership boundaries with other participants in the ecosystem and lead to
- 318 measurable results.

319 **2.1.1.2 Confidence**

- 320 SOA-based systems should enable service providers and consumers to conduct their business with the
- 321 appropriate level of confidence in the interaction. Confidence is especially important in situations that are
- 322 high-risk; this includes situations involving multiple ownership domains as well as situations involving the 323 use of sensitive resources.
- 324 Confidence has many dimensions: confidence in the successful interactions with other participants,
- 325 confidence in the assessment of trust, as well as confidence that the ecosystem is properly managed.

326 **2.1.1.3 Scalability**

- 327 The third goal of this reference architecture is scalability. In architectural terms, we determine scalability in
- terms of the smooth growth of complex systems as the number and complexity of services and
- 329 interactions between participants increases. Another measure of scalability is the ease with which 330 interactions can cross ownership boundaries.

331 2.1.2 Critical Success Factors

- A critical success factor (CSF) is a property of the intended system, or a sub-goal that directly supports a goal and there is strong belief that without it the goal is unattainable. CSFs are not necessarily
- measurable in themselves. As illustrated in Figure 1, CSFs can be associated with more than one goal.
- In many cases, critical success factors are often denoted by adjectives: reliability, trustworthiness, and so on. In our analysis of the SOA paradigm, however, it seems more natural to identify four critical concepts
- 337 (nouns) that characterize important aspects of SOA:

338 **2.1.2.1 Action**

- Participants' principal mode of participation in a SOA ecosystem is action; typically action in the interest of
 achieving some desired real world effect. Understanding how action is related to SOA is thus critical to
- the paradigm.

342 2.1.2.2 Trust

- 343 The viability of a SOA ecosystem depends on participants being able to effectively measure the
- 344 trustworthiness of the system and of participants. Trust is a private assessment of a participant's belief in 345 the integrity and reliability of the SOA ecosystem (see Section 3.1.4).

- 346 Trust can be analyzed in terms of trust in infrastructure facilities (otherwise known as reliability), trust in
- 347 the relationships and effects that are realized by interactions with services, and trust in the integrity and
- 348 confidentiality of those interactions particularly with respect to external factors (otherwise known as
- 349 security).
- 350 Note that there is a distinction between trust in a SOA-based system and trust in the capabilities
- accessed via the SOA-based system. The former focuses on the role of SOA-based systems as a
- 352 *medium* for conducting business, the latter on the trustworthiness of participants in such systems. This
- 353 architecture focuses on the former, while trying to encourage the latter.

354 2.1.2.3 Interaction

In order for a SOA ecosystem to function, it is essential that the means for participants to interact with each other is available throughout the system. Interaction encompasses not only the mechanics and

357 semantics of communication but also the means for discovering and offering communication.

358 2.1.2.4 Control

Given that a large-scale SOA-based system may be populated with many services, and used by large numbers of people; managing SOA-based systems properly is a critical factor for engendering confidence in them. This involves both managing the services themselves and managing the relationships between people and the SOA-based systems they are utilizing; the latter being more commonly identified with governance.

- The governance of SOA-based systems requires decision makers to be able to set policies about
- participants, services, and their relationships. It requires an ability to ensure that policies are effectively
 described and enforced. It also requires an effective means of measuring the historical and current
- 367 performances of services and participants.
- The scope of management of SOA-based systems is constrained by the existence of multiple ownership domains.

2.2 Principles of this Reference Architecture Foundation

371 The following principles serve as core tenets that guided the evolution of this reference architecture.

372 Technology Neutrality

- 373 Statement: Technology neutrality refers to independence from particular technologies.
- 374Rationale:We view technology independence as important for three main reasons: technology375specific approach risks confusing issues that are technology specific with those that are376integrally involved with realizing SOA-based systems; and we believe that the principles377that underlie SOA-based systems have the potential to outlive any specific technologies378that are used to deliver them. Finally, a great proportion of this architecture is inherently379concerned with people, their relationships to services on SOA-based systems and to380each other.
- Implications: The Reference Architecture Foundation must be technology neutral, meaning that we
 assume that technology will continue to evolve, and that over the lifetime of this
 architecture that multiple, potentially competing technologies will co-exist. Another
 immediate implication of technology independence is that greater effort on the part of
 architects and other decision makers to construct systems based on this architecture is
 needed.

387 Parsimony

- 388Statement:Parsimony refers to economy of design, avoiding complexity where possible and
minimizing the number of components and relationships needed.
- Rationale: The hallmark of good design is parsimony, or "less is better." It promotes better
 understandability or comprehension of a domain of discourse by avoiding gratuitous
 complexity, while being sufficiently rich to meet requirements.
- 393 Implications: Parsimoniously designed systems tend to have fewer but better targeted features.
 - soa-ra-v1.0-csd01 Standards Track Work Product Copyright © OASIS Open 2011. All Rights Reserved.

394 Distinction of Concerns

- 395Statement:Distinction of Concerns refers to the ability to cleanly identify and separate out the396concerns of specific stakeholders in such a way that it is possible to create architectural397models that reflect those stakeholders' viewpoint. In this way, an individual stakeholder or398a set of stakeholders that share common concerns only see those models that directly399address their respective areas of interest.
- Rationale: As SOA-based systems become more mainstream and increasingly complex, it will be important for the architecture to be able to scale. Trying to maintain a single, monolithic architecture description that incorporates all models to address all possible system stakeholders and their associated concerns will not only rapidly become unmanageable with rising system complexity, but it will become unusable as well.
- 405 Implications: This is a core tenet that drives this reference architecture to adopt the notion of 406 architectural viewpoints and corresponding views. A viewpoint provides the formalization 407 of the groupings of models representing one set of concerns relative to an architecture, 408 while a view is the actual representation of a particular system. The ability to leverage an 409 industry standard that formalizes this notion of architectural viewpoints and views helps 410 us better ground these concepts for not only the developers of this reference architecture but also for its readers. The IEEE Recommended Practice for Architectural Description 411 412 of Software-Intensive Systems [ANSI/IEEE 1471-2000::ISO/IEC 42010-2007] is the standard that serves as the basis for the structure and organization of thisdocument. 413

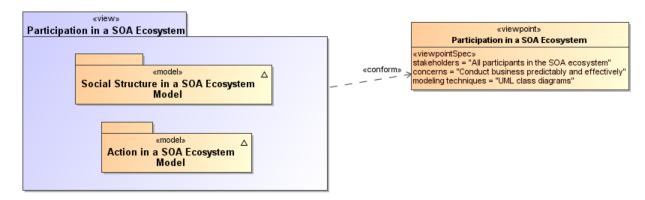

414 Applicability

- 415 Statement: Applicability refers to that which is relevant. Here, an architecture is sought that is
 416 relevant to as many facets and applications of SOA-based systems as possible; even those yet unforeseen.
- 418Rationale:An architecture that is not relevant to its domain of discourse will not be adopted and thus419likely to languish.
- Implications: The Reference Architecture Foundation needs to be relevant to the problem of matching
 needs and capabilities under disparate domains of ownership; to the concepts of "Intranet
 SOA" (SOA within the enterprise) as well as "Internet SOA" (SOA outside the enterprise);
 to the concept of "Extranet SOA" (SOA within the extended enterprise, i.e., SOA with
 suppliers and trading partners); and finally, to "net-centric SOA" or "Internet-ready SOA."

3 Participation in a SOA Ecosystem View 425 426 No man is an island 427 No man is an island entire of itself; every man 428 is a piece of the continent, a part of the main; 429 if a clod be washed away by the sea, Europe 430 is the less, as well as if a promontory were, as 431 well as any manner of thy friends or of thine own were; any man's death diminishes me, 432 433 because I am involved in mankind. 434 And therefore never send to know for whom 435 the bell tolls; it tolls for thee. 436 John Donne 437 438 The OASIS SOA Reference Model defines Service Oriented Architecture (SOA) as "a paradigm for 439 organizing and utilizing distributed capabilities that may be under the control of different ownership domains" and services as "the mechanism by which needs and capabilities are brought together". The 440 441 central focus of SOA is "the task or business function – getting something done." 442 Together, these ideas describe an environment in which business functions (realized in the form of 443 services) address business needs. Service implementations utilize capabilities to produce specific (real world) effects that fulfill those business needs. Both the people³ using the services, and the capabilities 444 themselves, may be distributed across ownership domains, with different policies and conditions of use in 445 446 force- this environment is referred to as a SOA Ecosystem. 447 The role of a service in the SOA context is to enable effective business solutions in this environment. Any 448 technology system created to deliver a service in such an environment is referred to as a SOA-based 449 system. SOA is thus a paradigm that guides the identification, design, implementation (i.e., organization), and utilization of such services. 450 451 A SOA-based system is concerned with how actors in a system interact to deliver a specific result - the 452 delivery of a capability or real-world effect. The SOA ecosystem is concerned with all potential stakeholders and the roles that they can play; how some stakeholders' needs are satisfied by other 453 454 stakeholders' solutions; how stakeholders assess risk; how they relate to each other through policies and contracts; and how they communicate and establish relationships of trust in the processes leading to the 455 456 delivery of a specific result. The Participation in a SOA Ecosystem view in the SOA-RAF focuses on the constraints and context in 457 458 which people conduct business using a SOA-based system. By business we mean any shared activity 459 entered into whose objective is to satisfy particular needs of each participant. The OASIS SOA RM 460 defines SOA as "a paradigm for organizing and utilizing distributed capabilities that may be under the 461 control of different ownership domains." To put it another way, to effectively employ the SOA paradigm, 462 the architecture must take into account the fact and implications of different ownership domains, and how best to organize and utilize capabilities that are distributed across those different ownership domains. 463 These are the main architectural issues that the Participating in a SOA Ecosystem view tries to address. 464

³ 'People' and 'person' must be understood as both human actors and 'legal persons', such as companies, who have rights and responsibilities similar to 'natural persons' (humans)

- 465 The subsections below expand on the completely abstract reference model by identifying more fully and
- with more specificity what challenges need to be addressed in order to successfully apply the SOA
- paradigm. Although this section does not provide a specific recipe, it does identify the important things
 that need to be thought about and resolved within an ecosystem context.
- that need to be thought about and resolved within an ecosystem context.
- The people actively participating in a SOA-based system, together with others who may potentially benefit
- from the services delivered by the system, together constitute the **stakeholders**. The stakeholders, the
- system and the environment (or context) within which they all operate, taken together forms the **SOA**
- 472 **ecosystem**. That ecosystem may reflect the SOA-based activities within a particular enterprise or of a
- wider network of one or more enterprises and individuals. Although a SOA-based system is essentially an
 IT concern, it is nonetheless a system engineered deliberately to be able to function in a SOA ecosystem.
- 475 In this context, a service is the mechanism that brings a SOA-based system capability together with
- 476 stakeholder needs in the wider ecosystem. This is explored in more detail in Section 3.2.2 below.
- Furthermore, this *Participation in a SOA Ecosystem* view helps us understand the importance of
 execution context the set of technical and business elements that allow interaction to occur in, and thus
 business to be conducted using, a SOA-based system.
- 480 This view describes how a SOA-based system behaves when participants may be in different
- organizations, with different rules and expectations, and assumes that the primary motivation for
- 482 participants to interact with each other is to achieve **objectives** –to get things done.
- 483 The dominant mode of communication within a SOA ecosystem is electronic, supported by IT resources
- 484 and artifacts. The stakeholders are nonetheless people: since there is inherent indirection involved when
- 485 people and systems interact using electronic means, we lay the foundations for how *communication* can
- be used to represent and enable action. However, it is important to understand that these
- communications are usually a means to an end and not the primary interest of the participants of theecosystem.
- 489 Several interdependent concerns are important in our view of a SOA-ecosystem. The ecosystem includes
- 490 stakeholders who are participants in the development, deployment and governance and use of a system
 491 and its services; or who may not participate but are nonetheless are affected by the system. Actors –
- 491 whether stakeholder **participants** or delegates who act only on behalf of participants (without themselves
- 493 having any stake in the actions that they have been tasked to perform) are engaged in **actions** which
- have an impact on the real world and whose meaning and intent are determined by implied or agreed-to
 semantics.
- 496 The main models in this view are:
- 497 the Social Structure in a SOA Ecosystem Model introduces the key elements that underlie the relationships between participants and that must be considered as pre-conditions in order to effectively bring needs and capabilities together across ownership boundaries;
- the Action in a SOA Ecosystem Model introduces the key concepts involved in service actions, and shows how joint action and real-world effect are what is being aimed for in a SOA ecosystem..

503

504 Figure 2 - Model elements described in the Participation in a SOA Ecosystem view

3.1 Social Structure in a SOA Ecosystem Model

506 The actions undertaken by participants in a SOA ecosystem are performed in a social context that defines

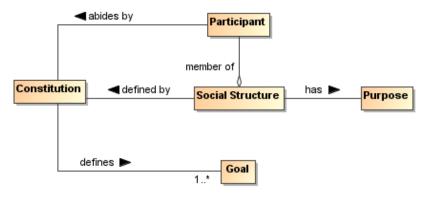

507 the relationships between the participants. That context is the social structure. In order to achieve

508 success in applying the SOA paradigm, the overall social structure in which the SOA effort is to be

509 undertaken must be taken into consideration. Ownership boundaries and their implications can only be

510 understood and addressed within the context of the larger social structure within which they exist and the

- 511 nature of the relationships between the different participants in that structure.
- 512 The primary function of the Social Structure Model is to explain the relationships between an individual
- 513 participant and the social context of that participant. The model also helps in defining and understanding
- the implications of crossing ownership boundaries. It is, for example, the foundation for understanding
- 515 security, governance and management in the SOA ecosystem.

- 516
- 517 Figure 3 Social Structure

518 Social Structure

519 A social structure⁴ is a nexus of relationships amongst participants brought together for a specific 520 purpose.

A social structure represents a collection of participants and is established with an implied or explicitly defined purpose. The purpose is usually reflected in specific goals laid down in the social structure's constitution or other 'charter'.

A social structure may have any number of participants and a large number of different relationships may exist among participants. The organizing principle for these relationships is the social structure's purpose. In addition, a given participant can be a member of multiple social structures. Thus, there may

- 527 be interaction among social structures, sometimes resulting in disagreements when the premises of the 528 social structures do not align.
- 529 A social structure can take different forms. For example, an enterprise is a common kind of social
- 530 structure that embodies a form of hierarchic organization; an online chat room represents a social
- 531 structure of peers that is very loose. A market represents a social structure of buyers and sellers. The
- 532 legal frameworks of entire countries and regions also count as social structures.
- 533 The RAF is concerned primarily with social structures that reflect relationships amongst **participants** in 534 SOA ecosystems, notably:

⁴ Social structures are sometimes referred to as social institutions.

- the enterprise social structure which is composed internally of many participants but that has sufficient cohesiveness to be considered as a potential stakeholder in its own right; and
 - the peer group which governs relationship between participants within an ecosystem..

538 Enterprise

537

539 An enterprise is a social structure with an identifiable leadership structure, and that has internally 540 established goals that reflect a defined purpose. It can act as a participant within other social 541 structures, including other enterprises and is represented by members of its leadership structure.

542 Peer Group

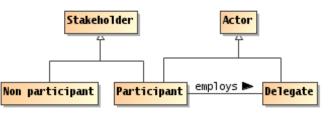

- 543 A peer group is a social structure with no discernable leadership structure, that may or may not 544 have internally established goals, but is identiable as the locus of interaction between participants 545 with individual goals seeking common outcomes and who are considered peers of one another.
- 546 Many interactions between participants take place within social structures. Depending on the scale and
- internal structure of an enterprise social structure, these interactions may or may not cross ownership
 boundaries (an enterprise can itself be composed of sub-enterprises). However, interactions between
- 549 participants within a peer social structure inherently cross ownership boundaries.
- 550 The nature and extent of the interactions that take place will reflect, often implicitly, degrees of trust
- between participants and the very specific circumstances of each participant at the time, and over the
- 552 course, of the interactions. It is in the nature of a SOA ecosystem that these relationships are rendered
- 553 more explicit and are formalized and form a central part of what the SOA-RM refers to as Execution 554 Context.
- 555 Social structures involved in a particular interaction are not always explicitly identified. For example, when
- 556 a customer buys a book over the Internet, the social structure that determines the validity of the
- transaction is often the legal framework of the region associated with the book vendor. Such legal
- 558 jurisdiction qualification is typically buried in the fine print of the service description.

559 Constitution

- 560 A constitution is a set of rules, written or unwritten, that spell out the purpose, goals, scope, and 561 functioning of a social structure.
- 562 Every social structure functions according to rules by which participants interact with each other within the 563 structure. In some cases, this is based on an explicit agreement, in other cases participants behave as
- though they agree to the constitution without a formal agreement. In still other cases, participants abide
- 565 by the rules with some degree of reluctance, such as governance of SOA-based systems, covered below. 566 In all cases, the constitution may change over time, in those cases of implicit agreement the change can
- 567 occur quickly.

568 3.1.1 Participants, Actors and Delegates

- 569 Social structures have **Stakeholders** people some of whom may be enterprises. They interact within 570 the broad SOA ecosystem. **Actors** on the other hand operate strictly within a SOA-based system.
- 571 There is also the concept of **Participant** which is particularly important as it reflects the hybrid role of a 572 person who is both a Stakeholder in the ecosystem (and thus primarily concerned with expressing needs 573 and seeing those needs fulfilled) *and* an Actor in the System (and thus directly involved with system-level
- 574 activity.
 - 575 A stakeholder can be either a participant (and thus also an actor with a specific functional role in a SOA-
 - 576 based system); or a non-participant someone who, without participating, nonetheless has something at 577 stake within the ecosystem.
- 578 An actor can be either a **participant** (and thus also a stakeholder with a stake in the ecosystem); or a
- 579 delegate a human actor with no stake in the specific action delegated or some automated agent –
- 580 acting on behalf of a participant.
- 581 The hybrid role of Participant provides a bridge between the wider (real-world) ecosystem the world of
- 582 the stakeholder and the more specific (usually technology-focused) system the world of the actor.

583

584 Figure 4 - Actors, Participants and Delegates

585 Stakeholder

586 A stakeholder in the SOA ecosystem is a person with an interest – a 'stake' – in the ecosystem.

Note: Not all stakeholders necessarily participate in the SOA ecosystem; indeed, the interest of nonparticipant stakeholders may be in realizing the benefits of a well-functioning ecosystem and not suffering unwanted consequences. They can not all or always be identified in advance but due account is often taken of such stakeholder types, including potential customers, beneficiaries, affected third parties, as well as potential "negative stakeholders" who might deliberately seek a negative impact on the ecosystem (such as hackers or criminals).

- 593 Actor
- 594 An actor is a human or non-human agent capable of action within a SOA-based system.

595 Participant

596 A participant is a person⁵ who is both a stakeholder in the SOA ecosystem and an actor in the 597 SOA-based system.

598 Delegate

599

600 A delegate can be a person or an automated or semi-automated agent.

601 Many stakeholders and actors operate in a SOA ecosystem, including software agents that permit people 602 to offer, and interact with, services; delegates that represent the interests of other participants; or security 603 agents charged with managing the security of the ecosystem. Note that automated agents are always

delegates, in that they act on behalf of a stakeholder.

In the different models of the RAF, actor is used when it is not important whether the entity is a delegate or a participant. If the actor is acting on behalf of a stakeholder, then we use delegate. This underlines the importance of delegation in SOA-based systems, whether the delegation is of work procedures carried out by human agents who have no stake in the actions with which they are tasked but act on behalf of a participant who does; or whether the delegation is performed by technology (automation). If the actor is

609 participant who does; or whether the delegation is performed by tech 610 also a stakeholder in the ecosystem, then we use participant.

611 In order for a delegate to act on behalf of another person, they must be able to act and have the authority 612 to do so.

A delegate is an actor that is acting on behalf of a participant.

⁵ Again, this can be a 'natural' or 'legal' person

3.1.2 Roles in Social Structures 613

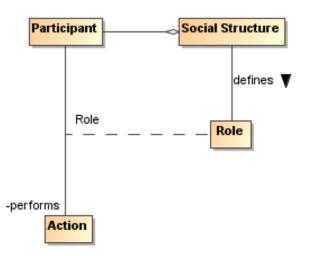

614 Social structures are abstractions: a social structure cannot directly perform actions - only people or

automated processes following the instructions of people can actually do things. However, an actor may 615

616 act on behalf of a social structure and certainly acts within a social structure depending on the roles that the actor assumes and the nature of the relationships between the concerned parties or stakeholders.

617

618

- 619
- 620 Figure 5 - Role in Social Structures
- 621 Role

622 A role is a type of relationship between a participant and the actions that the participant may 623 perform (or is allowed to perform) within a social structure.

624 A role is not immutable and is often time-bound. A participant can have one or more roles concurrently and may change them over time and in different contexts, even over the course of a particular interaction. 625

626

627 One participant with appropriate authority in the social structure may formally designate a role for another 628 participant, with associated rights and responsibilities, and that authority may even qualify a period during

629 which the designated role may be valid. In addition, while many roles are clearly identified, with

630 appropriate names and definitions of responsibilities, it is also possible to separately bestow rights,

631 bestow or assume responsibilities and so on, often in a temporary fashion. For example, when a

632 company president delegates certain responsibilities on another person, this does not imply that the other person has become company president. Likewise, a company president may bestow on someone else 633

634 her role during a period of time that she is on vacation or otherwise unreachable, with the understanding 635 that she will re-assume the role when she returns from vacation.

636 Conversely, someone who exhibits qualification and skill may assume a role without any formal 637 designation. For example, an office administrator who has demonstrated facility with personal computers may be known as (and thus assumed to role of) the 'goto' person for people who need help with their 638

- 639 computers.

640 Authority

Authority is the right to act on behalf of an organization or another person.

642 Right

641

- 643 A right is a predetermined permission conferred upon an actor to perform some action or assume a role in relation to the social structure. 644
- 645 Rights can be constrained. For example, sellers might have a general right to refuse service to potential customers but this right could be constrained so as to be exercised only when certain criteria are met. 646

647 Responsibility

- 648 A responsibility is a predetermined obligation on a participant to perform some action or assume 649 a role in relation to other participants.
- 650 Responsibility implies human agency, which is why only participants, as opposed to all actors (who can 651 be non-human agents) are concerned. This applies even if the consequences of such responsibility can 652 impact other (human and non-human) actors. Having authority often implies having responsibility.
- 653 Rights, authorities, responsibilities and roles form the foundation for the security model as well as 654 contributing to the governance model in the 'Ownership in a SOA Ecosystem' View of the RAF.
- 655 People will assume and perform roles according to their actual or perceived rights and responsibilities,
- 656 with or without explicit authority. In the context of a SOA ecosystem, human abilities and skills are
- relevant as they equip individuals with knowledge, information and tools that may be necessary to have
- 658 meaningful and productive interactions with a view to achieving a desired outcome. For example, a
- 659 person who needs a particular book, and has both the right and responsibility of purchasing the book from
- a given bookseller, will not have that need met from the online delegate of that bookstore if he does not know how to use a web browser. Equally, just because someone does have the requisite knowledge or
- 662 skills does not entitle them *per se* to interact with a specific system.
- 663 Two important types of constraints that are relevant to a SOA ecosystem are Permission and Obligation.

664 **Permission**

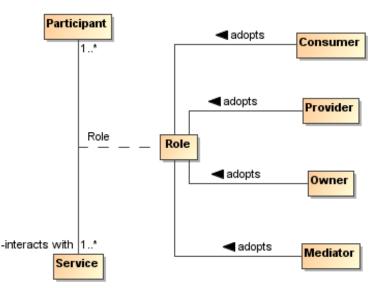

- 665 A permission is a constraint that identifies **actions** that an actor is (or is not) allowed to perform 666 and/or the **states** in which the actor is (or is not) permitted.
- Note that permissions are distinct from ability and from authority. Authority refers to the legitimate nature of an action as performed by an actor on behalf of a social structure. Ability refers to whether an actor has the capacity to perform the action. Permission does not always involve acting on behalf of anyone, nor
- does it imply or require the capacity to perform the action.

671 **Obligation**

- 672 An obligation is a constraint that prescribes the actions that an actor must (or must not) perform 673 and/or the states the actor must (or must not) attain or maintain.
- An example of obligations is the case where the service consumer and provider have entered into an agreement to provide and consume a service such that the consumer is obligated to pay for the service
- and the provider is obligated to provide the service based on the terms of the contract.
- 677 An obligation can also be a requirement to to *maintain* a given state. This may range from a requirement 678 to maintain a minimum balance on an account to a requirement that a service provider 'remember' that a 679 particular service consumer is logged in.
- Both permissions and obligations can be identified ahead of time, but only Permissions can be validated a
- priori: before the intended action or before entering the constrained state. Obligations can only be
- validated a posteriori through some form of auditing or verification process.

683 3.1.2.1 Service Roles

- As in roles generically, a participant can play one or more of those roles inherent to the SOA paradigm in the SOA ecosystem, depending on the context. A participant may be playing a role of a service provider in one relationship while simultaneously playing the role of a consumer in another. Roles inherent to the
- 687 SOA paradigm include Consumer, Provider, Owner, and Mediator.

688

689 Figure 6 - Participant Roles in a Service

690 Provider

691 A provider is a role assumed by a participant who is offering a service.

692 Consumer

693 A consumer is a role assumed by a participant who is interacting with a service in order to fulfill a 694 need.

695 Mediator

696 A mediator is a role assumed by a participant to facilitate interaction and connectivity in the 697 offering and use of services.

698 Owner

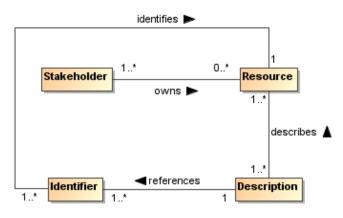

- 699 An owner is a role assumed by a participant who is claiming and exercising ownership over a 700 service.
- 701 It is a common understanding that service interactions are typically initiated by service consumers, 702 although this is not necessarily true in all situations. Additionally, as with service providers, several
- stakeholders may be involved in a service interaction supporting a given consumer.
- 704 The roles of service provider and service consumer are often seen as symmetrical, which is also not entirely correct. A consumer tends to express a 'Need' in non-formal terms: "I want to buy that book". The 705 706 type of 'Need' that a service is intended to fulfill has to be formalized and encapsulated by designers and 707 developers as a 'Requirement'. This Requirement should then be reflected in the target service, as a 708 'Capability'that, when accessed via a service, delivers a 'Real World Effect' to an arbitrary user: "The 709 chosen book is ordered for the user." It thus satisfies the need that has been defined for an archetypal 710 user. Specific and particular users may not experience a need exactly as captured by the service: "I don't want to pay that much for the book", "I wanted an eBook version", etc. There can therefore be a process 711 of implicit and explicit negotiation between the user and the service, aimed at finding a 'best fit' between 712 713 the user's specific need and the capabilities of the service that are available and consistent with the 714 service provider's offering. This process may continue up until the point that the user is able to accept 715 what is on offer as being the best fit and finally 'invokes' the service. 'Execution context' has thus been established. This is explored in more detail later on. Service mediation by a participant can take many 716 717 forms and may invoke and use other services in order to fulfill such mediation. For example, it might use a 718 service registry in order to identify possible service partners; or, in our book-buying example, it might provide a price comparison service, suggest alternative suppliers, different language editions or delivery 719
- 720 options.

721 3.1.3 Resource and Ownership

722 **3.1.3.1 Resource**

A resource is generally understood as an asset: it has value to someone. Key to this concept in a SOA

- ecosystem is that a resource needs to be identifiable.
- 725

726

729

727 Figure 7 - Resources

728 Resource

A resource is any identifiable entity that has value to a stakeholder.

A resource may be identifiable by different methods but within a SOA ecosystem a resource must have at
 least one well-formed identifier that may be unambiguously resolved to the intended resource.

732 Codified (but not *implied*) contracts, policies, obligations, and permissions are all examples of resources,

- as are capabilities, services, service descriptions, and SOA-based systems. An *implied* policy, contract,
- obligation or permission would not be a resource, even though it may have value to a stakeholder,
- 735 because it is not an identifiable entity.

736 Identifier

An identifier is any sequence of characters that may be unambiguously resolved to identifying a
 particular resource.

739 Identifiers typically require a context in order to establish the connection with the resource. In a SOA

- ecosystem, it is good practice to use globally unique identifiers; for example globally unique
- 741 Internationalized Resource Identifiers (IRIs).
- A given resource may have multiple identifiers, with different value for different contexts.
- 743 The ability to identify a resource is important in interactions to determine such things as rights and
- authorizations, to understand what functions are being performed and what the results mean, and to
- ration ensure repeatability or characterize differences with future interactions. Many interactions within a SOA
- ecosystem take place across ownership boundaries and the combination of interactions can be
- unpredictable. Identifiers provide the means for all resources important to a given SOA system to be
- 748 *unambiguously* identifiable at any moment and in any interaction.

749 3.1.3.2 Ownership

750 Ownership is defined as a relationship between a stakeholder and a resource, where some stakeholder

(in a role as **owner**) has certain claims with respect to the resource.

Typically, the ownership relationship is one of control: the owner of a **resource** can control some aspect of the resource.

754 Ownership

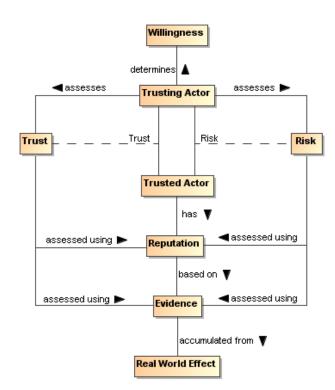

- Ownership is a particular set of claims, expressed as rights and responsibilities, that a
 stakeholder has in relation to a resource; It may include the right to transfer that ownership, or
 some subset of rights and responsibilities, to another entity.
- To own a resource implies taking responsibility for creating, maintaining and, if it is to be available to others, provisioning the resource. More than one stakeholder may own different rights or responsibilities associated with a given service, such as one stakeholder having the responsibility to deploy a capability as a service, another owning the rights to the profits that result from charging consumers for using the service, and yet another owning the right to use the service. There may also be joint ownership of a
- 763 resource, where the rights and responsibilities are shared.
- A stakeholder who owns a resource may delegate some or all of these rights and responsibilities to others, but typically retains the responsibility to see that the delegated rights and responsibilities are exercised as intended
- A crucial property that distinguishes ownership from a more limited *right to use* is the right to transfer
- rights and responsibilities totally and irrevocably to another stakeholder. When a stakeholder uses a
- resource but does not own the resource, that stakeholder may not transfer the right to use the resource to a third stakeholder. The owner of the resource maintains the rights and responsibilities of being able to
- authorize other stakeholders to use the owned resource.
- 772 Ownership is defined in relation to the social structure relative to which the given rights and
- responsibilities are exercised. For example, there may be constraints on how ownership may be
- transferred, such as a government may not permit a corporation to transfer assets to a subsidiary in adifferent jurisdiction.

776 **Ownership Boundary**

- An ownership boundary is the extent of ownership asserted by a stakeholder over a set of
 resources and for which rights and responsibilities are claimed and (usually) recognized by other
 stakeholders.
- In a SOA ecosystem, providers and consumers of services may be, or may be acting on behalf of,
 different owners, and thus the interaction between the provider and the consumer of a given service will
- 782 necessarily cross an ownership boundary. It is important to identify these ownership boundaries in a
- 50A ecosystem, as successfully crossing them requires the elements identified in the following sections
- be addressed. Addressing the elements identified in the following sections is referred to in the OASIS
- 785 SOA RM as establishing the execution context.

786 3.1.4 Trust and Risk

For an interaction to occur each actor must be able and **willing** to participate.

- 788
- 789 Figure 8 Willingness and Trust

790 Willingness

791 Willingness is the internal commitment of a human actor to carry out its part of an interaction.

Willingness to interact is not the same as a willingness to perform requested actions, however. For
example, a service provider that rejects all attempts to perform a particular action may still be fully willing
and engaged in interacting with the consumer. Important considerations in establishing willingness are
both trust and risk.

- 796 Trust
- 797 Trust is a private assessment or internal perception of one actor that another actor will perform 798 actions in accordance with an assertion regarding a desired real world effect.

799 **Risk**

800 Risk is a private assessment or internal perception of the likelihood that certain undesirable real 801 world effects will result from actions taken and the consequences or implications of such.

Trust is involved in all interactions – it is necessary for *all* participants (consumers, providers, mediators) involved in a given interaction to trust all involved actors, at least to the extent required for continuance of the interaction. The degree and nature of that trust is likely to be different for each actor, most especially when those actors are in different ownership boundaries.

An actor perceiving risk may take actions to mitigate that risk. At one extreme this will result in a refusal to interact. Alternately, it may involve adding protection – for example by using encrypted communication and/or anonymization – to reduce the perception of risk. Often, standard procedures are put in place to increase trust and to mitigate risk.

810 **3.1.4.1 Assessing Trust and Risk**

811 The assessments of trust and risk are based on evidence available to the *trusting* participant. In general,

- 812 participants will seek evidence directly from the *trusted* actor (e.g., via documentation provided via the
- 813 service description) as well as evidence of the reputation of the trusted actor (e.g., third-party annotations
- such as consumer feedback).

- 815 Trust is based on the confidence that the trusting participant has accurately and sufficiently gathered and 816 assessed evidence to the degree appropriate for the situation being assessed.
- 817 Assessment of trust is rarely binary. An actor is not completely trusted or untrusted because there is
- 818 typically some degree of uncertainty in the accuracy or completeness of the evidence or the assessment.
- 819 Similarly, there may be uncertainty in the amount and potential consequences of risk.
- 820 The relevance of trust to interaction depends on the assessment of risk. If there is little or no perceived
- 821 risk, or the risk can be covered by another party who accepts responsibility for it, then the degree of trust
- 822 may be less or not relevant in assessing possible actions. For example, most people consider there to be 823 an acceptable level of risk to privacy when using search engines, and submit gueries without any sense
- 824 of trust being considered.
- 825 As perceived risk increases, the issue of trust becomes more of a consideration. For interactions with a 826 high degree of risk, the trusting participant will typically require stronger or additional evidence when evaluating the balance between risk and trust. An example of high-risk is where a consumer's business 827 is dependent on the provider's service meeting certain availability and security requirements. If the 828 829 service fails to meet those requirements, the service consumer will go out of business. In this example, 830 the consumer will look for evidence that the likelihood of the service not meeting the performance and
- 831 security requirements is extremely low.

3.1.5 Policies and Contracts 832

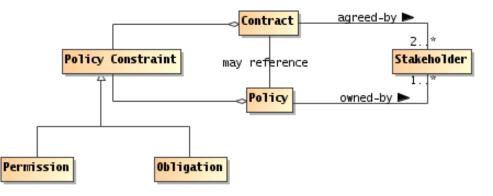

833 As noted in the Reference Model, a policy represents some commitment and/or constraint advertised

834 and enforced by a stakeholder and that stakeholder alone. A contract, on the other hand, represents an

835 agreement by two or more participants. Enforcement of contracts may or may not be the responsibility of

836 the parties to the agreement but is usually performed by a stakeholder in the ecosystem (public authority,

837 legal system, etc.).

838

839 Figure 9 - Policies and Contracts

- 840 Policy
- 841 A policy is an assertion made by a stakeholder which the stakeholder commits to uphold and, if 842 possible and necessary, enforce through stated constraints.

843 Policies can often be said to be about something – they have an object. For example, there may be 844 policies about the use of a service. Policies have an owner - the stakeholder who asserts and takes

responsibility for the policy. Note that the policy owner may or may not be the owner of the object of the 845 846 policy. Thirdly, policies represent constraints – some measurable limitation on the state or behavior of the

847 object of the policy, or of the behavior of the stakeholders owning the policy.

848 Contract

849 A contract represents an agreement made by two or more participants (the contracting parties) on a set of conditions (or contractual terms) together with a set of constraints that govern their 850

- behavior and/or state in fulfilling those conditions. 851
- 852 A service provider's policy may become a service provider/consumer contract when a service consumer 853 agrees to the provider's policy. That agreement may be formal, or may be informal. If a consumer's

- policy and a provider's policy are mutually exclusive, then some form of negotiation (involving human
- 855 interactions) or mediation must resolve the mutual exclusion before the service consumer/provider 856 interaction can occur. Note, this also applies if the policy is introduced by the consumer instead of the
- 856 Interaction can occur. Note, this also applies if the policy is introduced by the consumer instead of the 857 provider.
- 858 Both policies and contracts imply a desire to see constraints respected and enforced. Policies are owned
- by service providers individual (or aggregate) stakeholders and contracts are owned by both service
- 860 providers and consumers the parties to the contract; these stakeholders are responsible for ensuring
- that any constraints in the policy or contract are enforced, although the actual enforcement may be
- delegated to a different mechanism. A contract does not necessarily oblige the contracting parties to act
- 863 (for example to use a service) but it does constrain how they act if and when the condition covered by the
- 864 contract occurs (for example, when a service is invoked and used).

865 **3.1.6 Communication**

866 Communication

- 867 A communication is a process of reaching mutual understanding, in which participants not only 868 exchange information as messages but share the meaning of this information.
- A communication involves at least one actor in the role of **sender** and at least one other actor in the role of **recipient**. All actors must perform their role in order for the communication to occur.
- A given communication may involve any number of **recipients**. In some situations, the sender may not be
- aware of the recipient. However, without both a sender and a recipient there is no communication. A
- given communication does not necessarily involve interaction between the actors; it can be a simple oneway transmission requiring no further action by the recipient. However, interaction does, necessarily,
- 875 involve communication.
- 876 A communication involves a message, which an actor receiving must be able to correctly interpret. The
- 877 extent of that correct interpretation depends on the role of the actor and the purpose of the
- 878 communication.
- A communication is not effective unless the recipient can correctly interpret the message (or at least, that part of it which is relevant to the participant). However, interpretation can itself be characterized in terms
- 881 of semantic engagement: the proper understanding of a message in a given context.
- We can characterize the necessary modes of interpretation in terms of a shared understanding of a common vocabulary (or mediation among vocabularies) and of the purpose of the communication. More formally, we can say that a communication has a combination of message and purpose.
- 885 Interactions between service consumers and providers do not need to resemble human speech. Machine-
- 886 machine communication is typically highly stylized in form, it may have particular forms and it may involve
- 887 particular terms not found in everyday human communication.

888 **3.1.7 Semantics and Semantic Engagement**

- A SOA ecosystem is a space in which actors need to share understanding⁶ as well as sharing actions.
 Indeed, such shared understanding is a pre-requisite to a joint action being carried out as intended. It is
- vital to a trusted and effective ecosystem. Semantics are therefore pervasive throughout SOA

⁶ We use a mechanical, Turing test-based approach to understanding here: if an actor behaves as though it understands an utterance then we assume that it does understand it.

- ecosystems and important in communicative actions described above, as well as a driver for policies and
 other aspects of the ecosystem.
- 894 In order to arrive at shared understanding, an actor must effectively process and understand assertions in
- a manner appropriate to the particular context. An assertion, in general, is a measurable and explicit
 statement made by an actor. In a SOA ecosystem, in particular, assertions are concerned with the 'what'
 and the 'why' of the state of the ecosystem and its actors.
- Understanding and interpreting those assertions allows other actors to know what may be expected of
 them in any particular joint action. An actor can potentially 'understand' an assertion in a number of ways,
 but it is specifically the process of arriving at a *shared* understanding that is important in the ecosystem.
 This process is semantic engagement among the actors in the SOA ecosystem. It can be instantaneous
 or progressively achieved. It is important that there is a level of engagement appropriate to the particular
 context.

904 Semantic Engagement

- 905 Semantic engagement is the process by which an actor engages with a set of assertions based 906 on that actor's interpretation and understanding of those assertions.
- 907 Different actors have differing capabilities and requirements for understanding assertions. This is true for 908 both human and non-human actors. For example, a purchase order process does not require that a 909 message forwarding agent 'understand' the purchase order, but a processing agent does need to 910 'understand' the purchase order in order to know what to with the order once received.
- 911 The impact of any assertion can only be fully understood in terms of specific social contexts that
- 912 necessarily include the actors that are involved. For example, a policy statement that governs the actions

913 relating to a particular resource may have a different impact or purpose for the participant that owns the

- 914 resource than for the actor that is trying to access it: the former understands the purpose of the policy as
- 915 a statement of enforcement the latter understands it as a statement of constraint.

916 **3.2 Action in a SOA Ecosystem Model**

917 Participants cannot always achieve desired results by leveraging resources in their own ownership 918 domain. This unfulfilled need leads them to seek and leverage services provided by other participants and 919 using resources beyond their ownership and control. The participants identify service providers with which 920 they think they can interact to achieve their objective and engage in joint action with those other actors 921 (service providers) in order to bring about the desired outcome. The SOA ecosystem provides the

- 922 environment in which this happens.
- 923 An action model is put forth a-priori by the service provider, and is effectively an undertaking by the
- service provider that the actions identified in the action model and invoked consistent with the process
 model will result in the described real world effect. The action model describes the actions leading to a
- 926 real-world effect. A potential service consumer who is interested in a particular outcome to satisfy their
- 927 need must understand those actions as capable of achieving that desired outcome.
- 928 When the consumer "invokes" a service, a joint action is started as identified in the action model, 929 consistent with the temporal sequence as defined by the process model, and where the consumer and
- the provider are the two parties of the joint action. Additionally, the consumer can be assured that the
- identified real-world effects will be accomplished through evidence provided via the service description.
- Since the service provider does not know about all potential service consumers, the service provider may
 also describe what additional constraints are necessary in order for the service consumer to invoke
- 934 particular actions, and thus participate in the joint action. These additional constraints, along with others
- that might not be listed, are preconditions for the joint action to occur and/or continue (as per the process
- model), and are referred to in the SOA RM as execution context. Execution context goes all the way from
- 937 human beings involved in aligning policies, semantics, network connectivity and communication
- 938 protocols, to the automated negotiation of security protocols and end-points as the individual actions 939 proceed through the process model.
- Also, it is important to note that both actions and RWE are 'fractal' in nature, in the sense that they can
- 941 often be broken down into more and more granularity depending on how they are examined and what 942 level of detail is important.

- All of these things are important to getting to the core of participants' concern in a SOA ecosystem: the
- ability to leverage resources or capabilities to achieve a desired outcome, and in particular where those
 resources or capabilities do not belong to them or are beyond their direct control. i.e., that are outside of
- 946 their ownership boundary.
- 947 In order to use such resources, participants must be able to identify their own needs in the form of
- requirements, identify and compose into a business solution those resources or capabilities that will meet
 their needs, and engage in joint action the coordinated set of actions that participants pursue in order to
 achieve measurable results in furtherance of their goals.
- In order to act in a way that is appropriate and consistent, participants must communicate with each other
 about their own goals, objectives and policies, and those of others. This is the main concern of Semantic
 Engagement.
- A key aspect of joint action revolves around the trust that both parties must exhibit in order to participate in the joint action. The willingness to act and a mutual understanding of both the information exchanged
- and the expected results is the particular focus of Sections 3.1.4 and 3.1.7.

957 3.2.1 Needs, Requirements and Capabilities

Participants in a SOA ecosystem often need other participants to *do* something, leveraging a capability
 that they do not themselves possess. For example, a customer requiring a book may call upon a service
 provider to deliver the book. Likewise, the service provider needs the customer to pay for it.

- 961 There is a reason that participants are engaged in this activity: different participants have different needs
- and have or apply different **capabilities** for satisfying them. These are core to the concept of a service.
- 963 The SOA-RM defines a service as "the mechanism by which needs and capabilities are brought
- together". This idea of services being a mechanism "between" needs and capabilities was introduced in
- 965 order to emphasize capability as the notional or existing business functionality that would address a well-
- defined need. Service is therefore the *implementation* of such business functionality *such that it is accessible* through a well-defined interface. A capability that is isolated (i.e., it is inaccessible to potential
- 968 consumers) is emphatically not a service.
- 969 Business functionality
- 970 Business functionality is a defined set of business-aligned tasks that provide recognizable business value 971 to 'consumer' stakeholders and possibly others in the SOA ecosystem.
- 972 The idea of a service in a SOA ecosystem combines business functionality with implementation, including
- 973 the artifacts needed and made available as IT resources. From the perspective of software developers, a
- 974 SOA service enables the use of capabilities in an IT context. For the consumer, the service (combining
- business functionality and implementation) generates intended real world effects. The consumer is not
- 976 concerned with the underlying artifacts which make that delivery possible.
- 977 In a SOA context, the consumer (as a stakeholder) expresses a need ("I want to buy a book") and looks
 978 to an appropriate service to fulfill that need and assesses issues such as the trustworthiness, intent and
 979 willingness of a particular provider. This ecosystem communication continues up to the point when the
- 980 consumer is ready to act. The consumer (as an actor now) will then interact with a provider by invoking a
- 981 service (for example, ordering the book using an online bookseller) and engaging in relevant actions
- 982 (validating the purchase, submitting billing and delivery details) within the system with a view to achieving
- 983 the desired Real World Effect (having the book delivered).

984 **Need**

985 A need is a general statement expressed by a stakeholder of something deemed necessary. It
986 may be formalized as one or more **requirements** that must be fulfilled in order to achieve a
987 stated goal.

988 Requirement

989 A requirement is a formal statement of a desired result (a real world effect) that, if achieved, will 990 satisfy a need.

- This requirement can then be used to create a capability that in turn can be brought to bear to satisfy that
- need. Both the requirement and the capability to fulfill it are expressed in terms of desired real world
- 993 effect.
- 994 Capability
- 995 A capability is an ability to deliver a real world effect.

996 The Reference Model makes a distinction between a capability (as a *potential* to deliver the real world 997 effect) and the ability of bringing that capability to bear (via a realized service) as the realization of the 998 real world effect.

999 **3.2.2 Services Reflecting Business**

The SOA paradigm often emphasizes the interface through which service interaction is accomplished.
 While this enables predictable integration in the sense of traditional software development, the prescribed interface alone does not guarantee that services will be composable into business solutions.

1003 Business solution

1004 A **business solution** is a set of defined interactions that combine implemented or notional 1005 business functionality in order to address a set of business needs.

1006 Composability

- 1007**Composability** is the ability to combine individual services, each providing defined business1008functionality, so as to provide more complex business solutions.
- To achieve composability, capabilities must be identified that serve as building blocks for business solutions. In a SOA ecosystem, these building blocks are captured as services representing well-defined business functions, operating under well-defined policies and other constraints, and generating welldefined real world effects. These service building blocks should be relatively stable so as not to force repeated changes in the compositions that utilize them, but should also embody SOA attributes that readily support creating compositions that can be varied to reflect changing circumstances.
- 1015 The SOA paradigm emphasizes both composition of services and opacity of how a given service is 1016 implemented. With respect to opacity, the SOA-RM states that the service could carry out its described
- 1017 functionality through one or more automated and/or manual processes that in turn could invoke other 1018 available services.
- 1019 Any composition can itself be made available as a service and the details of the business functionality, 1020 conditions of use, and effects are among the information documented in its service description.
- 1021 Composability is important because many of the benefits of a SOA approach assume multiple uses for
- 1022 services, and multiple use requires that the service deliver a business function that is reusable in multiple
- business solutions. Simply providing a Web Service interface for an existing IT artifact does not, in
- 1024 general, create opportunities for sharing business functions. Furthermore, the use of tools to auto-
- 1025 generate service software interfaces will not guarantee services than can effectively be used within
- 1026 compositions if the underlying code represents programming constructs rather than business functions. In
- such cases, services that directly expose the software details will be as brittle to change as the underlying
- 1028 code and will not exhibit the characteristic of loose coupling.

1029 **3.2.3 Action, Communication and Joint Action**

In general terms, entities act in order to achieve their goals. However, the form of action that is of most
 interest within a SOA ecosystem is that involving interaction across ownership boundaries (between more
 than one actor) – joint action.

1033 **3.2.3.1 Action and Actors**

1034 **Action**

1035

An action is the application of intent to cause an effect.

- 1036 The aspect of action that distinguishes it from mere force or accident is that someone *intends* that the
- 1037 action achieves a desired objective or effect. This definition of action is very general. In the case of SOA, 1038 we are mostly concerned with actions that take place within a system and have specific effects on the
- 1038 we are mostly concerned with actions that take place within a system and have specific effects on the 1039 SOA ecosystem – what we call **Real World Effects**. The actual real world effect of an action, however,
- 1040 may go beyond the intended effect.
- 1041 Objectives refer to real world effects that participants believe are achievable by a specific action or set of 1042 actions that deliver appropriate changes in shared state. In contrast, a goal is not expressed in terms of
- 1043 specific action but rather in terms of desired end state.
- 1044 For example, someone may wish to have enough light to read a book. In order to satisfy that goal, the
- 1045 reader walks over to flip a light switch. The *objective* is to change the state of the light bulb, by turning on 1046 the lamp, whereas the *goal* is to be able to read. The *real world effect* is more light being available to
- 1047 enable the person to read.
- 1048 While an effect is any measurable change resulting from an action, a SOA ecosystem is concerned more 1049 specifically with real world effects.

1050 Real World Effect

1051A real world effect is a measurable change to the shared state of pertinent entities, relevant to
and experienced by specific stakeholders of an ecosystem.

1053 This implies measurable change in the overall state of the SOA ecosystem. In practice, however, it is 1054 specific state changes of certain entities that are relevant to particular participants that constitute the real 1055 world effect as experienced by those participants.

1056 3.2.3.2 Communication and Joint Actions

- 1057 In this Reference Architecture Foundation, we are concerned with two levels of activity: as communication 1058 and as participants engaged in joint actions to use and offer services.
- 1059 In order for multiple actors to participate in a joint action, they must each act according to their role within 1060 the joint action. This is achieved through communication and messaging.
- 1061 Communication the formulation, transmission, receipt and interpretation of messages is the
- foundation of all joint actions within the SOA ecosystem, given the inherent separation often across
 ownership boundaries of actors in the system.
- 1064 Communication between actors requires that they play the roles of 'sender' or 'receiver' of messages as
- 1065 appropriate to a particular action although it is not necessarily required that they both be active 1066 simultaneously.
- 1067 An actor sends a message in order to communicate with other actors. The communication itself is often
- 1068 not intended as part of the desired real world effect but rather includes messages that seek to establish, 1069 manage, monitor, report on, and guide the joint action throughout its execution.
- 1070 Like communication, joint action usually involves different actors. However, joint action resulting from
- the deliberate actions undertaken by different actors *intentionally* impacts shared state within the
- 1072 system leading to real world effects.

1073 Joint Action

- 1074Joint action is the coordinated set of actions involving the efforts of two or more actors to achieve1075an effect.
- 1076 Note that the effect of a joint action is *not* always equivalent to one or more effects of the individual 1077 actions of the participating actors, i.e., it may be more than the sum of the parts.
- 1078 Different viewpoints lead to either communication or joint action as being considered most important. For 1079 example, from the viewpoint of ecosystem security, the integrity of the communications may be dominant;
- 1079 example, from the viewpoint of ecosystem security, the integrity of the communications may be dominant.

1081 **3.2.4 State, Shared State and Real-World Effect**

1082 State

- 1083 State is the condition of an entity at a particular time.
- 1084 State is characterized by a set of facts that is true of the entity. In principle, the total state of an entity (or 1085 the world as a whole) is unbounded. In practice, we are concerned only with a subset of the State of an entity that is measurable and useful in a given context. 1086
- 1087 For example, the total state of a lightbulb includes the temperature of the filament of the bulb. It also 1088 includes a great deal of other state - the composition of the glass, the dirt that is on the bulb's surface and so on. However, an actor may be primarily interested in whether the bulb is 'on' or 'off' and not on the 1089 amount of dirt accumulated. That actor's characterization of the state of the bulb reduces to the fact: 'bulb 1090 1091 is now on'.
- 1092 In a SOA ecosystem, there is a distinction between the set of facts about an entity that only that entity can access - the so-called Private State - and the set of facts that may be accessible to other actors in the 1093 1094 SOA-based system - the public or Shared State.

1095 **Private State**

1096 The private state is that part of of an entity's state that is knowable by, and accessible to, only that entity. 1097

1098 Shared State

1115

1116

1119

1120

1121

1126

- 1099 Shared state is that part of an entity's state that is knowable by, and may be accessible to, other 1100 actors.
- 1101 Note that shared state does not imply that the state is accessible to all actors. It simply refers to that 1102 subset of state that may be accessed by other actors. Generally this will be the case when actors need to 1103 participate in joint actions.
- 1104 It is the aggregation of the shared states of pertinent entities that constitutes the desired effect of a joint
- 1105 action. Thus the change to this shared state is what is experienced in the wider ecosystem as a real world 1106 effect

3.3 Architectural Implications 1107

3.3.1 Social structures 1108

- 1109 A SOA ecosystem's participants are organized into various forms of social structure. Not all social
- structures are hierarchical: a SOA ecosystem should be able to incorporate peer-to-peer forms of 1110 1111 organization as well as hierarchic structures. In addition, it should be possible to identify and manage any 1112 constitutional agreements that define the social structures present in a SOA ecosystem.
- 1113 Different social structures have different rules of engagement but predictable behavior is one of 1114 the underpinnings of trust. This therefore requires mechanisms to:
 - express constitutions and other organizing principles of participants; 0
 - inherit rules of engagement from parent to child social structures. 0
- Social structures have roles and members and this impacts who may be authorized to act and in 1117 • 1118 what circumstances. This requires mechanisms to:
 - identify and manage members of social structures 0
 - Identify and manage attributes of the members 0
 - describe roles and role adoption 0
- 1122 Social structures overlap and interact, giving rise to situations in which rules of engagement may 1123 conflict. In addition, a given actor may be member of multiple social structures and the social 1124 structures may be associated with different jurisdictions. This requires mechanisms to: 1125
 - identify the social structures that are active during a series of joint actions; 0
 - identify and resolve conflicts and inconsistencies. 0

1127 3.3.2 Resource and Ownership

1128 Communication about and between, visibility into, and leveraging of resources requires the unambiguous 1129 identification of those resources. Ensuring unambiguous identities implies

- Mechanism for assigning and guaranteeing uniqueness of globally unique identifiers
- Identifying the extent of the enterprise over which the identifier needs to be understandable and unique
- Mechanism and framework for ensuring the long-livedness of identifiers (i.e., they cannot just change arbitrarily)

1135 **3.3.3 Policies and Contracts**

1136 1137 1138 1139 1140 1141 1142 1143 1144 1145	 Policies are constraints Policies MUST be expressed Constraints MUST be enforceable Manage,emt of potentially large numbers of policies MUST be achievable Policies have owners Policies SHOULD be established by social structures. Policies may not be consistent with one another Policy conflict resolution techniques MUST exist and be in place Agreements are constraints agreed to Contracts SHOULD be enforced by mechanisms of the social structure
1146	3.3.4 Communications as a Means of Mediating Action
1147	Using message exchange for mediating action implies
1148 1149 1150 1151 1152	 Ensuring correct identification of the structure of messages: Identifying the syntax of the message; Identifying the vocabularies used in the communication Identifying the higher-level structure of the communication, such as policy assertion, contract enforcement, etc.
1153 1154 1155 1156	 A principal objective of communication is to mediate action Messages convey actions and events Receiving a message is an action, but is not the same action as the action conveyed by the message
1157 1158 1159 1160	 Actions are associated with objectives of the actors involved Explicit representation of objectives may facilitate automated processing of messages An actor agreeing to adopt an objective becomes responsible for that objective

1161 **3.3.5 Semantics**

Semantics is pervasive in a SOA ecosystem. There are many forms of utterance that are relevant to the
ecosystem: apart from communicated content there are policy statements, goals, purposes, descriptions,
and agreements which are all forms of utterance.

- 1165 The operation of the SOA ecosystem is significantly enhanced if
- A careful distinction is made between public semantics and private semantics. In particular, it
 MUST be possible for actors to process content such as communications, descriptions and
 policies solely on the basis of the public semantics of those utterances.
- A well founded semantics ensures that any assertions that are essential to the operator of the ecosystem (such as policy statements, and descriptions) have carefully chosen written expressions and associated decision procedures.
- The role of vocabularies as a focal point for multiple actors to be able to understand each other is critical. While no two actors can fully share their interpretation of elements of vocabularies, ensuring that they do understand the public meaning of vocabularies' elements is essential.

1175 **3.3.6 Trust and Risk**

1176 In traditional systems, the balance between trust and risk is achieved by severely restricting interactions1177 and by controlling the participants of a system.

- 1178 It is important that actors are able to explicitly reason about both trust and risk in order to effectively
- 1179 participate in a SOA ecosystem. The more open and public the SOA ecosystem is, the more important it 1180 is for actors to be able to reason about their participation.

1181 **3.3.7 Needs, Requirements and Capabilities**

- 1182 In the process of capturing needs as requirements, and the subsequent requirements decomposition and 1183 allocation processes need to be informed by capabilities that already exist.
- Architecture needs to
- 1185
- Take into account existing capabilities available as services

1186 3.3.8 The Importance of Action

- 1187 Participants participate in a SOA ecosystem in order to get their needs met. This involves action; both 1188 individual actions and joint actions.
- 1189 Any architectural realization of a SOA ecosystem should address:
- How actions are modeled:
- 1191 o Identifying the performer or agent of the action;
- 1192 the target of the action; and the
- 1193 o verb of the action.
- 1194 Any explicit models of joint action should take into account
- The choreography that defines the joint action.
- The potential for multiple joint actions to be layered on top of each other

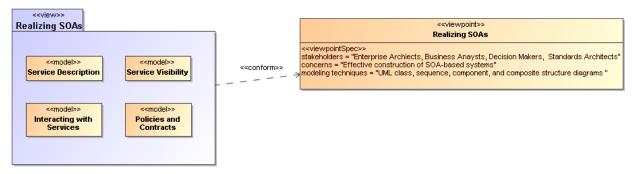

1197 **4 Realization of a SOA Ecosystem view**

- 1198
- 1199
- 1200

Make everything as simple as possible but no simpler. Albert Einstein

1201 The *Realization of a SOA Ecosystem* view focuses on elements that are needed to support the discovery 1202 of and interaction with services. The key questions asked are "What are services, what support is needed 1203 and how are they realized?"

1204 The models in this view include the Service Description Model, the Service Visibility Model, the Interacting 1205 with Services Model, and the Policies and Contracts Model.

1206

- 1207 Figure 10 Model Elements Described in the Realization of a SOA Ecosystem view
- 1208 The Service Description Model informs the participants of what services exist and the conditions under 1209 which they can be used. Some of those conditions follow from policies and agreements on policy that flow
- from the Policies and Contracts Model. The information in the service description as augmented by
- 1211 details of policy provides the basis for visibility as defined in the SOA Reference Model and captured in
- 1212 the Service Visibility Model. Finally, the process by which services as described are used under the
- 1213 defined conditions and agreements is described in the Interacting with Services Model.

1214 **4.1 Service Description Model**

- 1215 A service description is an artifact, often document-based, that defines or references the information
- 1216 needed to use, deploy, manage and otherwise control a service. This includes not only the information
- 1217 and behavior models associated with a service that define the service interface but also includes
- 1218 information needed to decide whether the service is appropriate for the current needs of the service
- 1219 consumer. Thus, the service description should also include information such as service reachability,
 1220 service functionality, and the policies associated with a service.
- A service description artifact may be a single document or it may be an interlinked set of documents. For the purposes of this model, differences in representation are to be ignored, but the implications of a "web of documents" are discussed later in this section.
- 1224 There are several points to note regarding service description:
- The Reference Model states that one of the hallmarks of SOA is the large amount of associated description. The model presented below focuses on the description of services but it is equally important to consider the descriptions of the consumer, other participants, and needed resources other than services.
- Descriptions are inherently incomplete but may be determined as *sufficient* when it is possible for the participants to access and use the described services based only on the descriptions provided. This means that, at one end of the spectrum, a description along the lines of "That service on that machine" may be sufficient for the intended audience. On the other extreme, a service description with a machine-process-able description of the semantics of its operations

1234and real world effects may be required for services accessed via automated service discovery1235and planning systems.

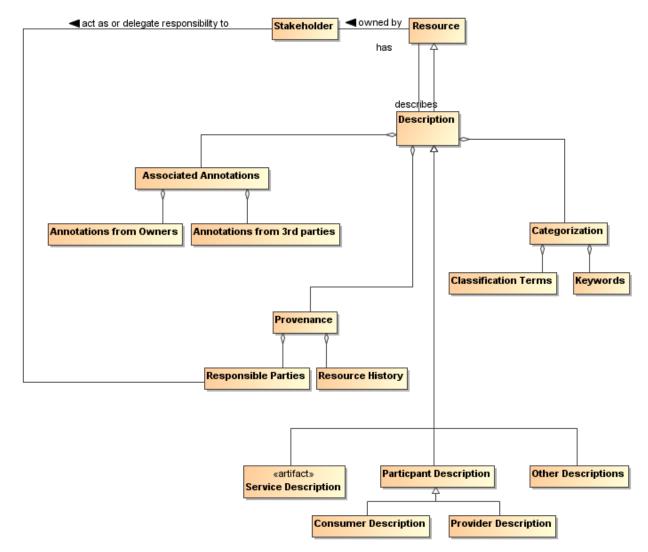

- 1236 Descriptions come with context, i.e. a given description comprises information needed to • adequately support the context. For example, a list of items can define a version of a service, but 1237 1238 for many contexts an indicated version number is sufficient without the detailed list. The current 1239 model focuses on the description needed by a service consumer to understand what the service does, under what conditions he service will do it, how well the service does it, and what steps are 1240 needed by the consumer to initiate and complete a service interaction. Such information also 1241 enables the service provider to clearly specify what is being provided and the intended conditions 1242 of use. 1243
- Descriptions change over time as, for example, the ingredients and nutrition information for food labeling continues to evolve. A requirement for transparency of transactions may require additional description for those associated contexts.
- Description always proceeds from a basis of what is considered "common knowledge". This may be social conventions that are commonly expected or possibly codified in law. It is impossible to describe everything and it can be expected that a mechanism as far reaching as SOA will also connect entities where there is inconsistent "common" knowledge.
- Descriptions become the collection point of information related to a service or any other resource, but it is not necessarily the originating point or the motivation for generating this information. In particular, given a SOA service as the access to an underlying capability, the service may point to some of the capability's previously generated description, e.g. a service providing access to a data store may also have access to information indicating the freshness of the data.
- 1256 These points emphasize that there is no one "right" description for all contexts and for all time. Several 1257 descriptions for the same subject may exist at the same time, and this emphasizes the importance of the 1258 description referencing source material maintained by that material's owner rather than having multiple 1259 copies that become out of synch and inconsistent.
- 1260 It may also prove useful for a description assembled for one context to cross-reference description
 1261 assembled for another context as a way of referencing ancillary information without overburdening any
 1262 single description. Rather than a single artifact, description can be thought of as a web of documents that
 1263 enhance the total available description.
- This Reference Architecture Foundation uses the term service description for consistency with the concept defined in the Reference Model. Some SOA literature treats the idea of a "service contract" as equivalent to service description. In the SOA-RAF, the term service description is preferred. Replacing the term "service description" with the term "service contract" implies that just one side of the interaction is governing and misses the point that a single set of policies identified by a service description may lead to numerous contracts, i.e. service level agreements, leveraging the same description.

1270 **4.1.1 The Model for Service Description**

Figure 11 shows Service Description as a subclass of the general Description class, where Description is a subclass of the resource class as defined in Section 3.1.3.1. In addition, each resource is assumed to have a description. The following section discusses the relationships among elements of general description and the subsequent sections focus on service description. Other descriptions, such as those of participants, are important to SOA but are not individually elaborated in this document.

1276 **4.1.1.1 Elements Common to General Description**

1277 The general Description class is composed of a number of elements that are expected to be common 1278 among all descriptions supporting a service oriented architecture. A registry often contains a subset of the 1279 description instance, where the chosen subset is identified as that which facilitates discovery. Additional 1280 information contained in a more complete description may be needed to initiate and continue interaction.

1283 Figure 11 - General Description

1284 **4.1.1.1 Provenance**

1285 While the resource Identifier provides the means to know which subject and subject description are being 1286 considered, Provenance as related to the Description class provides information that reflects on the 1287 quality or usability of the subject. Provenance specifically identifies the stakeholder (human, defined role, 1288 organization, ...) that assumes responsibility for the resource being described and tracks historic information that establishes a context for understanding what the resource provides and how it has 1289 changed over time. Responsibilities may be directly assumed by the stakeholder who owns a resource or 1290 the Owner may designate Responsible Parties for the various aspects of maintaining the resource and 1291 provisioning it for use by others. There may be more than one stakeholder identified under Responsible 1292 1293 Parties; for example, one stakeholder may be responsible for code maintenance while another is 1294 responsible for provisioning of the executable code.

1295 4.1.1.1.2 Keywords and Classification Terms

A traditional element of description has been to associate the resource being described with predefined
 keywords or classification taxonomies that derive from referenceable formal definitions and vocabularies.
 This Reference Architecture Foundation does not prescribe which vocabularies or taxonomies may be
 referenced, nor does it limit the number of keywords or classifications that may be associated with the

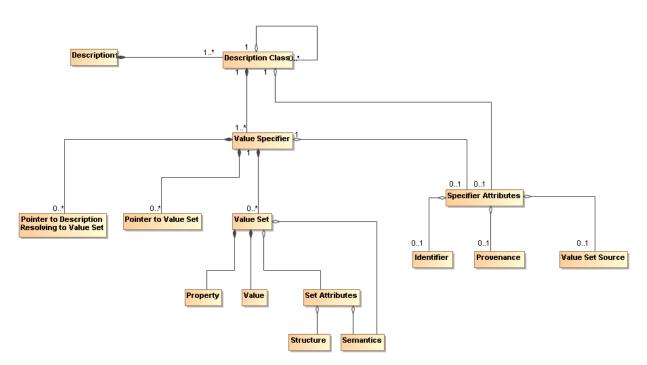

resource. It does, however, state that a normative definition of any terms or keywords SHOULD be
 referenced, whether that be a representation in a formal ontology language, a pointer to an online
 dictionary, or any other accessible source. See Section 4.1.1.2 for further discussion on associating
 semantics with assigned values.

1304 4.1.1.1.3 Associated Annotations

The general description instance may also reference associated documentation that is in addition to that considered necessary in this model. For example, the owner of a service may have documentation on best practices for using the service. Alternately, a third party may certify a service based on their own criteria and certification process; this may be vital information to other prospective consumers if they were willing to accept the certification in lieu of having to perform another certification themselves. Note, while the examples of Associated Documentation presented here are related to services, the concept applies equally to description of other entities.

1312 4.1.1.2 Assigning Values to Description Instances

1313

1314

1315 Figure 12 - Representation of a Description

1316 Figure 11 shows the template for a general description, but individual description instances depend on 1317 the ability to associate meaningful values with the identified elements. Figure 12 shows a model for a collection of information that provides for value assignment and traceability for both the meaning and the 1318 1319 source of a value. The model is not meant to replace existing or future schema or other structures that 1320 have or will be defined for specific implementations, but it is meant as guidance for the information such 1321 structures need to capture to generate sufficient description. It is expected that tools will be developed to 1322 assist the user in populating description and auto-filling many of these fields, and in that context, this 1323 model provides guidance to the tool developers.

In Figure 12, each class has an associated value specifier or is made up of components that eventually
resolve to a value specifier. For example, Description has several components, one of which is
Categorization, which would have an associated value specifier.

1327 A value specifier consists of

a collection of value sets with associated property-value pairs, pointers to such value sets, or
 pointers to descriptions that eventually resolve to value sets that describe the component; and

- attributes that qualify the value specifier and the value sets it contains.
- 1331 The qualifying attributes for the value specifier include
- an optional identifier that would allow the value set to be defined, accessed, and reused elsewhere;
- provenance information that identifies the party (individual, role, or organization) that has
 responsibility for assigning the value sets to any description component;
- an optional source of the value set, if appropriate and meaningful, e.g. if a particular data source is mandated.
- 1338 If the value specifier is contained within a higher-level component (such as Service Description containing 1339 Service Functionality), the component may assume values from the attributes of its container.
- Note, provenance as a qualifying attribute of a value specifier is different from provenance as part of an instance of Description. Provenance for a service identifies those who own and are responsible for the service, as described in Section 3.1.3. Provenance for a value specifier identifies who is responsible for choosing and assigning values to the value sets that comprise the value specifier. It is assumed that granularity at the value specifier level is sufficient and provenance is not required for each value set.
- 1345 The value set also has attributes that define its structure and semantics.
- The semantics of the value set property should be associated with a semantic context conveying
 the meaning of the property within the execution context, where the semantic context could vary
 from a free text definition to a formal ontology.
- For numeric values, the structure would provide the numeric format of the value and the
 "semantics" would be conveyed by a dimensional unit with an identifier to an authoritative source
 defining the dimensional unit and preferred mechanisms for its conversion to other dimensional
 units of like type.
 - For nonnumeric values, the structure would provide the data structure for the value representation and the semantics would be an associated semantic model.
 - For pointers, architectural guidelines would define the preferred addressing scheme.

1356 The value specifier may indicate a default semantic model for its component value sets and the individual 1357 value sets may provide an override.

1358 The property-value pair construct is introduced for the value set to emphasize the need to identify

1359 unambiguously both what is being specified and what is a consistent associated value. The further

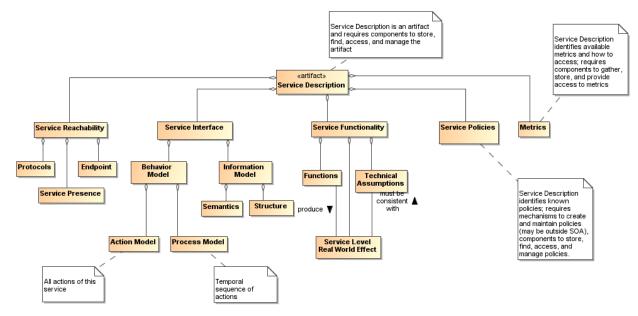

1360 qualifying of Structure and Semantics in the Set Attributes allows for flexibility in defining the form of the 1361 associated values.

1353

1354 1355

1362 4.1.1.3 Model Elements Specific to Service Description

1363

1364

1374

1375

1365 Figure 13 - Service Description

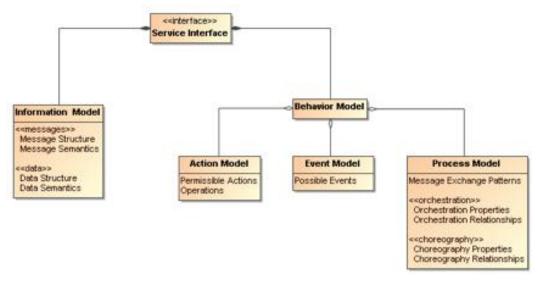

1366 The major elements for the Service Description subclass follow directly from the areas discussed in the 1367 Reference Model. Here, we discuss the detail shown in Figure 13 and the purpose served by each 1368 element of service description.

1369 Note, the intent in the subsections that follow is to describe how a particular element, such as the service 1370 interface, is reflected in the service description, not to elaborate on the details of that element.

1371 4.1.1.3.1 Service Interface

As noted in the Reference Model, the service interface is the means for interacting with a service. For theSOA-RAF and as shown in Section 4.3 the service interface supports an exchange of messages, where

- the message conforms to a referenceable message exchange pattern (MEP),
- the message payload conforms to the structure and semantics of the indicated information model,
- the messages are used to denote events or actions against the service, where the actions are
 specified in the action model and any required sequencing of actions is specified in the process
 model.

1379

1380 Figure 14 - Service Interface

- Note we distinguish the structure and semantics of the message from that of the underlying protocol that
 conveys the message. The message structure may include nested structures that are independently
 defined, such as an enclosing envelope structure and an enclosed data structure.
- 1384 These aspects of messages are discussed in more detail in Section 4.3.2.

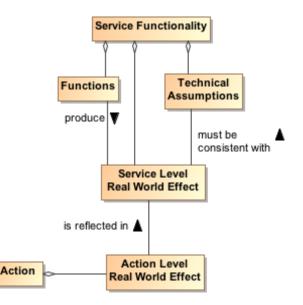

1385 4.1.1.3.2 Service Reachability

Service reachability, as modeled in Section 4.2.2.3 enables service participants to locate and interact with one another. To support service reachability, the service description should indicate the endpoints to which a service consumer can direct messages to invoke actions and the protocol to be used for message exchange using that endpoint.

As generally applied to an action, the endpoint is the conceptual location where one applies an action; with respect to service description, it is the actual address where a message is sent.

1392 4.1.1.3.3 Service Functionality

While the service interface and service reachability are concerned with the mechanics of using a service, service functionality and performance metrics (discussed in Section 4.1.1.3.4) describe what can be expected as a result of interacting with a service. Service Functionality, shown in Figure 13 as part of the overall Service Description model and extended in Figure 15, is a clear expression of service function(s) and the real world effects of invoking the function. The Functions represent business activities in some domain that produce the desired real world effects.

1400 Figure 15 - Service Functionality

The Service Functionality may also be limited by technical assumptions/constraints that underlie the effects that can result. Technical constraints are defined as domain specific restrictions and may express underlying physical limitations, such as flow speeds must be below sonic velocity or disk access that cannot be faster than the maximum for its host drive. Technical constraints are related to the underlying capability accessed by the service. In any case, the real world effects must be consistent with the technical assumptions/constraints.

1407 In Figure 13 and Figure 15, we specifically refer to Service Level and Action Level real world effects.

1408 Service Level Real World Effect

1409A service level real world effect is a specific change in the state or the information returned as a1410result of interacting with a service.

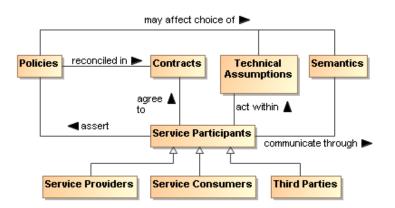

1411 Action Level Real World Effect

- 1412 An action level real world effect is a specific change in the state or the information returned as a 1413 result of interacting through a specific action.
- 1414 Service description describes the service as a whole while the component aspects should contribute to
- 1415 that whole. Thus, while individual Actions may contribute to the real world effects to be realized from
- 1416 interaction with the service, there would be a serious disconnect for Actions to contribute real world
- 1417 effects that could not consistently be reflected in the Service Level Real World Effects and thus the
- 1418 Service Functionality. The relationship to Action Level Real World Effects and the implications on 1419 defining the scope of a service are discussed in Section 4.1.2.1.
- 1420 Elements of Service Functionality may be expressed as natural language text, reference an existing 1421 taxonomy of functions or other formal model.

1422 4.1.1.3.4 Service Policies, Metrics, and Compliance Records

- 1423 Policies prescribe the conditions and constraints for interacting with a service and impact the willingness
- to continue visibility with the other participants. Whereas technical constraints are statements of "physical"
 fact, policies are subjective assertions made by the service provider (sometimes as passed on from
- 1426 higher authorities).
- 1427 The service description provides a central location for identifying what policies have been asserted by the
- service provider. The specific representation of the policy, e.g. in some formal policy language, is outside
- 1429 of the service description. The service description would reference the normative definition of the policy.

- 1430 Policies may also be asserted by other service participants, as illustrated by the model shown in Figure
- 1431 16. Policies that are generally applicable to any interaction with the service are asserted by the service
- 1432 provider and included in the Service Policies section of the service description.

1434 Figure 16 - Model for Policies and Contracts as related to Service Participants

1435 In Figure 16, we specifically refer to policies at the service level. In a similar manner to that discussed for

1436 Service Level vs. Action Level Real World Effects in Section 4.1.1.3.3, individual Actions may have

1437 associated policies stating conditions for performing the action, but these must be reflected in and be

1438 consistent with the policies made visible at the service level and thus the description of the service as a

1439 whole. The relationship to Action Level Policies and the implications on defining the scope of a service

1440 are discussed in Section 4.1.2.1.

1441 As noted in Figure 16, the policies asserted may be reflected as Technical Constraints that available

1442 services or their underlying capabilities must be capable of meeting; it may similarly affect the semantics

that can be used. For example of the former, there may be a policy that specifies the surge capacity to 1443

be accommodated by a server, but a service that is not designed to make use of the larger server 1444

1445 capacity would not satisfy the intent of the policy and would not be appropriate to use. For the latter, a 1446 policy may require that only services that support interaction via a community-sponsored vocabulary can

1447 be used.

1448 Contracts are agreements among the service participants. The contract may reconcile inconsistent 1449 policies asserted by the participants or may specify details of the interaction. Service level agreements

1450 (SLAs) are one commonly used category of contracts.

1451 The definition and later enforcement of policies and contracts are predicated on the potential for

1452 measurement; the relationships among the relevant concepts are shown in the model in Figure 17.

Performance Metrics identify quantities that characterize the speed and quality of realizing the real world 1453 effects produced using the SOA service; in addition, policies and contracts may depend on 1454

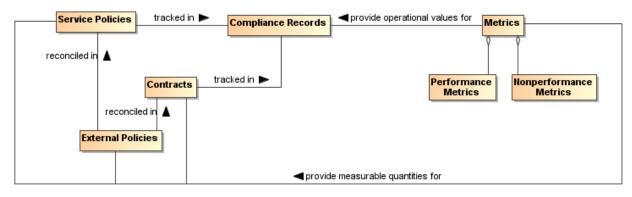

1455 nonperformance metrics, such as whether a license is in place to use the service. Some of these metrics

reflect the underlying capability, e.g. a SOA service cannot respond in two seconds if the underlying 1456

1457 capability is expected to take five seconds to do its processing; some metrics reflect the SOA service, e.g.

1458 the additional overhead introduced when making data access requests across the network.

1459

1461 Figure 17 - Policies and Contracts, Metrics, and Compliance Records

As with many quantities, the metrics associated with a service are not themselves defined by this Service

1463 Description Model because it is not known a priori which metrics are being collected or otherwise checked

by the services, the SOA infrastructure, or other resources that participate in the SOA interactions.

1465 However, the service description SHOULD provide a placeholder (possibly through a link to an externally

1466 compiled list) for identifying which metrics are available and how these can be accessed.

1467 The use of metrics to evaluate compliance is discussed in Section 4.1.1.3.4. The results of compliance 1468 evaluation SHOULD be maintained in compliance records and the means to access the compliance

records MAY be included in the Service Policies portion of the service description. For example, the

1470 description may be in the form of static information (e.g. over the first year of operation, this service had a

1471 91% availability), a link to a dynamically generated metric (e.g. over the past 30 days, the service has had

1472 a 93.3% availability), or access to a dynamic means to check the service for current availability (e.g., a

- 1473 ping). The relationship between service presence and the presence of the individual actions that can be
- 1474 invoked is discussed under Reachability in Section 4.2.2.3.

1475 Note, even when policies relate to the perspective of a single participant, policy compliance can be

1476 measured and policies may be enforceable without contractual agreement with other participants. While

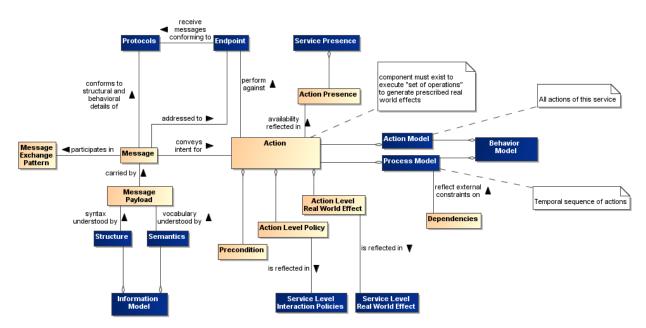

1477 certain elements of contracts and contract compliance are likely private, public aspects of compliance

1478 should be reflected in the compliance record information referenced in the service description.

1479 **4.1.2 Use of Service Description**

1480 **4.1.2.1 Service Description in support of Service Interaction**

1481 If we assume we have awareness, the service participants must still establish willingness and presence to 1482 ensure full visibility (See Section 4.2) and to interact with the service. Service description provides 1483 necessary information for many aspects of preparing for and carrying through with interaction. Recall the 1484 fundamental definition of service is a mechanism to access an underlying capability; the service 1485 description describes this mechanism and its use. It lays the groundwork for what can occur, whereas 1486 service interaction comprises the specifics through which real-world effects are realized.

1488 Figure 18 - Relationship between Action and Components of Service Description Modelx

Figure 18 combines the models in the subsections of Section 4.1.1 to concisely relate action and the relevant components of the Service Description model. The purpose of Figure 18 is to demonstrate that the components of service description go beyond arbitrary documentation and form the critical set of

information needed to define the what and how of action. In Figure 18, the leaf nodes from Figure 13 areshown in blue.

Action is typically invoked via a Message where the structure and behavioral details of the message

1495 conform to an identified Protocol and is directed to the address of the identified endpoint, and the
 1496 message payload conforms to the service Information Model.

The availability of an action is reflected in the Action Presence and each Action Presence contributes to
the overall Service Presence; this is discussed further in Section 4.2.2.3. Each action has its own
endpoint and also its own protocols associated with the endpoint⁷ and to some extent, e.g. current or

1500 average availability, there is presence for the action through that endpoint. The endpoint and service 1501 presence are also part of the service description.

An action may have preconditions where a Precondition is something that needs to be in place before an action can occur, e.g. confirmation of a precursor action. Whether preconditions are satisfied is evaluated when an actor tries to perform the action and not before. Presence for an action means an actor can initiate it and is independent of whether the preconditions are satisfied. However, the successful completion of the action may depend on whether its preconditions were satisfied.

Analogous to the relationship between actions and preconditions, the Process Model may imply Dependencies for succeeding steps in a process, e.g. that a previous step has successfully completed, or may be isolated to a given step. An example of the latter would be a dependency that the host server has scheduled maintenance and access attempts at these times would fail. Dependencies related to the

1510 scheduled maintenance and access attempts at these times would fail. Dependencies related to the

⁷ This is analogous to a WSDL 2.0 interface operation (WSDL 1.1 portType) having one or more defined bindings and the service identifies the endpoints (WSDL 1.1 ports) corresponding to the bindings.

- 1511 process model do not affect the presence of a service although these may affect whether the business 1512 function successfully completes.
- 1513 The conditions under which an action can be invoked may depend on policies associated with the action.
- 1514 The Action Level Policies MUST be reflected in (or subsumed by) the Service Policies because such
- policies may be critical to determining whether the conditions for use of the service are consistent with the
- 1516 policies asserted by the service consumer. The Service Policies are included in the service description.
- 1517 Similarly, the result of invoking an action is one or more real world effects, and any Action Level Real
- 1518 World Effects MUST be reflected in the Service Level Real World Effect included in the service
- 1519 description. The unambiguous expression of action level policies and real world effects as service
- 1520 counterparts is necessary to adequately describe what constitutes the service interaction.
- An adequate service description MUST provide a consumer with information needed to determine if the service policies, the (business) functions, and service-level real world effects are of interest, and there is nothing in the technical constraints that preclude use of the service.
- 1524 Note at the service level, the business functions are not concerned with the action or process models. 1525 These models are detailed separately.
- 1526 The service description is not intended to be isolated documentation but rather an integral part of service
- use. Changes in service description SHOULD immediately be made known to consumers and potential
 consumers.
- 1529 4.1.2.1.1 Description and Invoking Actions Against a Service
- At this point, let us assume the descriptions were sufficient to establish willingness; see Section 4.2.2.2.
 Figure 18 indicates the service endpoint establishes where to actually carry out the interaction. This is
 where we start considering the action and process models.
- The action model identifies the multiple actions a user can perform against a service and the user would perform these in the context of the process model as specified or referenced under the Service Interface portion of Service Description. For a given business function, there is a corresponding process model, where any process model may involve multiple actions. From the above discussion of model elements of description we may conclude (1) actions have reachability information, including endpoint and presence,
- 1538 (2) presence of service is some aggregation of presence of its actions, (3) action preconditions and 1539 service dependencies do not affect presence although these may affect successful completion.
- Having established visibility, the interaction can proceed. Given a business function, the consumer knows
 what will be accomplished (the service functionality), the conditions under which interaction will proceed
 (service policies and contracts), and the process that must be followed (the process model). The
- 1543 remaining question is how the description information for structure and semantics enable interaction.
- 1544 We have established the importance of the process model in identifying relevant actions and their
- 1545 sequence. Interaction proceeds through messages and thus it is the syntax and semantics of the 1546 messages with which we are here concerned. A common approach is to define the structure and
- 1547 semantics that can appear as part of a message; then assemble the pieces into messages; and,
- associate messages with actions. Actions make use of structure and semantics as defined in theinformation model to describe its legal messages.
- The process model identifies actions to be performed against a service and the sequence for performing the actions. For a given action, the Reachability portion of description indicates the protocol bindings that are available, the endpoint corresponding to a binding, and whether there is presence at that endpoint. An interaction is through the exchange of messages that conform to the structure and semantics defined in the information model and the message sequence conforming to the action's identified MEP. The result is some portion of the real world effect that must be assessed and/or processed (e.g. if an error exists, that part that covers the error processing would be invoked).

1557 4.1.2.1.2 The Question of Multiple Business Functions

Action level effects and policies MUST be reflected at the service level for service description to supportvisibility.

1560 It is assumed that a SOA service represents an identifiable business function to which policies can be

applied and from which desired business effects can be obtained. While contemporary discussions of

- 1562 SOA services and supporting standards do not constrain what actions or combinations of actions can or 1563 should be defined for a service, the SOA-RAF considers the implications of service description in defining
- 1564 the range of actions appropriate for an individual SOA service.

1565 Consider the situation if a given SOA service is the mechanism for access to multiple independent (but 1566 loosely related) business functions. These are not multiple effects from a single function but multiple 1567 functions with potentially different sets of effects for each function. A service can have multiple actions a user may perform against it, and this does not change with multiple business functions. As an individual 1568 1569 business function corresponds to a process model, so multiple business functions imply multiple process 1570 models. The same action may be used in multiple process models but the aggregated service presence would be specific to each business function because the components being aggregated may be different 1571 1572 between process models. In summary, for a service with multiple business functions, each function has 1573 (1) its own process model and dependencies, (2) its own aggregated presence, and (3) possibly its own list of policies and real world effects. 1574

- 1575 A common variation on this theme is for a single service to have multiple endpoints for different levels of 1576 quality of service (QoS). Different QoS imply separate statements of policy, separate endpoints, possibly 1577 separate dependencies, and so on. One could say the QoS variation does not require this because there 1578 can be a single QoS policy that encompasses the variations, and all other aspects of the service would be the same except for the endpoint used for each QoS. However, the different aspects of policy at the 1579 1580 service level would need to be mapped to endpoints, and this introduces an undesirable level of coupling across the elements of description. In addition, it is obvious that description at the service level can 1581 become very complicated if the number of combinations is allowed to grow. 1582
- 1583 One could imagine a service description that is basically a container for action descriptions, where each 1584 action description is self contained; however, this would lead to duplication of description components 1585 across actions. If common description components are factored, this either is limited to components 1586 common across all actions or requires complicated tagging to capture the components that often but do 1587 not universally apply.
- 1588 If a provider cannot describe a service as a whole but must describe every action, this leads to the 1589 situation where it may be extremely difficult to construct a clear and concise service description that can 1590 effectively support discovery and use without tedious logic to process the description and assemble the 1591 available permutations. In effect, if adequate description of an action begins to look like description of a 1592 service, it may be best to have it as a separate service.
- Recall, more than one service can access the same underlying capability, and this is appropriate if a
 different real world effect is to be exposed. Along these lines, one can argue that different QoS are
 different services because getting a response in one minute rather than one hour is more than a QoS
 difference; it is a fundamental difference in the business function being provided.
- As a best practice, a criteria for whether a service is appropriately scoped may be the ease or difficulty in creating an unambiguous service description. A consequence of having tightly-scoped services is there will likely be a greater reliance on combining services, i.e. more fundamental business functions, to create more advanced business functions. This is consistent with the principles of service oriented architecture and is the basic position of the Reference Architecture, although not an absolute requirement. Combining services increases the reliance on understanding and implementing the concepts of orchestration, choreography, and other approaches yet to be developed; these are discussed in more detail in section
- 1604 4.4 Interacting with Services.

1605 4.1.2.1.3 Service Description, Execution Context, and Service Interaction

The service description MUST provide sufficient information to support service visibility, including the willingness of service participants to interact. However, the corresponding descriptions for providers and consumers may both contain policies, technical assumptions, constraints on semantics, and other technical and procedural conditions that must be aligned to define the terms of willingness. The

- agreements which encapsulate the necessary alignment form the basis upon which interactions may
- 1611 proceed in the Reference Model, this collection of agreements and the necessary environmental
- 1612 support establish the execution context.

1613 To illustrate the concept of the execution context, consider a Web-based system for timecard entry. For

1614 an employee onsite at an employer facility, the execution context requires a computer connected to the 1615 local network and the employee must enter their network ID and password. Relevant policies include that

1616 the employee must maintain the most recent anti-virus software and virus definitions for any computer

1617 connected to the network.

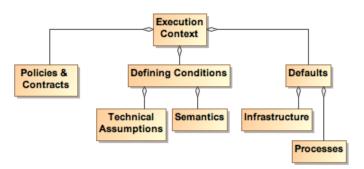

1618 For the same employee connecting from offsite, the execution context specifies the need for a computer

1619 with installed VPN software and a security token to negotiate the VPN connection. The execution context

also includes proxy settings as needed to connect to the offsite network. The employee must still comply

1621 with the requirements for onsite computers and access, but the offsite execution context includes 1622 additional items before the employee can access the same underlying capability and realize the same

1623 real world effect s, i.e. the timecard entries.

1624

1625 Figure 19 - Execution Context

1626 Figure 19 shows a few broad categories found in execution context. These are not meant to be

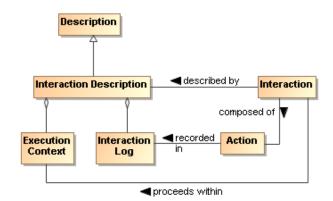

1627 comprehensive. Other items may need to be included to provide a sufficient description of the interaction
 1628 conditions. Any other items not explicitly noted in the model but needed to set the environment SHOULD
 1629 be included in the execution context.

1630 While the execution context captures the conditions under which interaction can occur, it does not capture 1631 the specific service invocations that do occur in a specific interaction. A service interaction as modeled in Figure 20 introduces the concept of an Interaction Description which is composed of both the Execution 1632 1633 Context and an Interaction Log. The execution context specifies the set of conditions under which the interaction occurs and the interaction log captures the sequence of service interactions that occur within 1634 the execution context. This sequence should follow the Process Model but can include details beyond 1635 1636 those specified there. For example, the Process Model may specify an action that results in identifying a data source, and the identified source is used in a subsequent action. The Interaction Log would record 1637 the specific data source used. 1638

1639 The execution context can be thought of as a container in which the interaction occurs and the interaction

1640 log captures what happens inside the container. This combination is needed to support auditability and

1641 repeatability of the interactions.

1642

1643 Figure 20 - Interaction Description

- SOA allows flexibility to accomplish both repeatability and reusability. In facilitating reusability, a service
 can be updated without disrupting the user experience of the service. So, Google can improve their
 ranking algorithm without notifying the user about the details of the update.
- However, it may also be vital for the consumer to be able to recreate past results or to generate consistent results in the future, and information such as what conditions, which services, and which versions of those services were used is indispensible in retracing one's path. The interaction log is a critical part of the resulting real world effects because it defines how the effects were generated and possibly the meaning of observed effects. This increases in importance as dynamic composability becomes more feasible. In essence, a result has limited value if one does not know how it was generated.
- 1654 The interaction log SHOULD be a detailed trace for a specific interaction, and its reuse is limited to 1655 duplicating that interaction. An execution context can act as a template for identical or similar 1656 interactions. Any given execution context MAY define the conditions of future interactions.
- 1657 Such uses of execution context imply (1) a standardized format for capturing execution context and (2) a 1658 subclass of general description could be defined to support visibility of saved execution contexts. The 1659 specifics of the relevant formats and descriptions are beyond the scope of this document.
- 1660 A service description is unlikely to track interaction descriptions or the constituent execution contexts or
- 1661 interaction logs that include mention of the service. However, as appropriate, linking to specific instances
- 1662 of either of these could be done through associated annotations.

1663 **4.1.3 Relationship to Other Description Models**

- 1664 While the representation shown in Figure 12 is derived from considerations related to service description, 1665 it is acknowledged that other metadata standards are relevant and should, as possible, be incorporated
- into this work. Two standards of particular relevance are the Dublin Core Metadata Initiative (DCMI)
 [DCMI] and ISO 11179 [ISO 11179], especially Part 5.
- 1668 When the service description (or even the general description class) is considered as the DCMI
- 1669 "resource", Figure 12 aligns nicely with the DCMI resource model. While some differences exist, these
- 1670 are mostly in areas where DCMI goes into detail that is considered beyond the scope of the current
- 1671 Reference Architecture. For example, DCMI defines classes of "shared semantics" whereas this
- 1672 Reference Architecture Framework considers that an identification of relevant semantic models is 1673 sufficient. Likewise, the DCMI "description model" goes into the details of possible syntax encodings
- 1674 whereas for the Reference Architecture Framework it is sufficient to identify the relevant formats.
- With respect to ISO 11179 Part 5, the metadata fields defined in that reference may be used without prejudice as the properties in Figure 12. Additionally, other defined metadata sets may be used by the service provider if the other sets are considered more appropriate, i.e. it is fundamental to this reference architecture to identify the need and the means to make vocabulary declarations explicit but it is beyond the scope to specify which vocabularies are to be used. In addition, the identification of domain of the
- 1680 properties and range of the values has not been included in the current Reference Architecture
- 1681 discussion, but the text of ISO 11179 Part 5 can be used consistently with the model prescribed in this 1682 document.
- 1683 Description as defined here considers a wide range of applicability and support of the principles of service 1684 oriented architecture. Other metadata models can be used in concert with the model presented here
- because most of these focus on a finer level of detail that is outside the present scope, and so provide a
 level of implementation guidance that can be applied as appropriate.

1687 4.1.4 Architectural Implications

1692

- 1688 The definition of service description indicates numerous architectural implications on the SOA ecosystem:
- It changes over time and its contents will reflect changing needs and context. This requires the existence of:
 mechanisms to support the storage, referencing, and access to normative definitions of
 - mechanisms to support the storage, referencing, and access to normative definitions of one or more versioning schemes that may be applied to identify different aggregations of

1693		descriptive information, where the different schemes may be versions of a versioning
1694		scheme itself;
1695		 configuration management mechanisms to capture the contents of each aggregation and
1696		apply a unique identifier in a manner consistent with an identified versioning scheme;
1697		 one or more mechanisms to support the storage, referencing, and access to conversion
1698		relationships between versioning schemes, and the mechanisms to carry out such
1699		conversions.
1700	• De	escription makes use of defined semantics, where the semantics may be used for
1701		tegorization or providing other property and value information for description classes. This
1702		quires the existence of:
1703		 semantic models that provide normative descriptions of the utilized terms, where the
1704		models may range from a simple dictionary of terms to an ontology showing complex
1705		relationships and capable of supporting enhanced reasoning;
1705		
1700		
1707		 configuration management mechanisms to capture the normative description of each semantic model and to apply a unique identifier in a manner consistent with an identified
1708		
		versioning scheme;
1710		 one or more mechanisms to support the storage, referencing, and access to conversion
1711		relationships between semantic models, and the mechanisms to carry out such
1712	_	conversions.
1713		escriptions include reference to policies defining conditions of use. In this sense, policies are
1714		so resources that need to be visible, discoverable, and accessible. This requires the existence
1715	of	(as also enumerated under governance):
1716		o description of policies, including a unique identifier for the policy and a sufficient, and
1717		preferably a machine processible, representation of the meaning of terms used to
1718		describe the policy, its functions, and its effects;
1719		\circ one or more discovery mechanisms that enable searching for policies that best meet the
1720		search criteria specified by the service participant; where the discovery mechanism has
1721		access to the individual policy descriptions, possibly through some repository
1722		mechanism;
1723		o accessible storage of policies and policy descriptions, so service participants can access,
1724		examine, and use the policies as defined.
1725	• De	escriptions include references to metrics which describe the operational characteristics of the
1726		bjects being described. This requires the existence of (as partially enumerated under
1727	go	vernance):
1728	-	 the infrastructure monitoring and reporting information on SOA resources;
1729		 possible interface requirements to make accessible metrics information generated;
1730		• mechanisms to catalog and enable discovery of which metrics are available for a
1731		described resources and information on how these metrics can be accessed;
1732		• mechanisms to catalog and enable discovery of compliance records associated with
1733		policies and contracts that are based on these metrics.
1734	• De	escriptions of the interactions are important for enabling auditability and repeatability, thereby
1735		tablishing a context for results and support for understanding observed change in performance
1736		results. This requires the existence of:
1737	51	 one or more mechanisms to capture, describe, store, discover, and retrieve interaction
1738		logs, execution contexts, and the combined interaction descriptions;
1739		 one or more mechanisms for attaching to any results the means to identify and retrieve
1740		the interaction description under which the results were generated.
1740		escriptions may capture very focused information subsets or can be an aggregate of numerous
1741		mponent descriptions. Service description is an example of an aggregate for which manual
1742		aintenance of the whole would not be feasible. This requires the existence of:
1743	1116	
1744		
1745		the composite description;
		 tools to facilitate identifying the sources of information to associate with the description
1747		elements;
1748		 tools to collect the identified description elements and their associated sources into a standard referenceable format that one support general associated sources into a
1749		standard, referenceable format that can support general access and understanding;
	soa-ra-v1.0-c	sd01 06 July 2011

1750 tools to automatically update the composite description as the component sources 0 1751 change, and to consistently apply versioning schemes to identify the new description 1752 contents and the type and significance of change that occurred. The description is the source of vital information in establishing willingness to interact with a 1753 resource, reachability to make interaction possible, and compliance with relevant conditions of 1754 use. This requires the existence of: 1755 one or more discovery mechanisms that enable searching for described resources that 1756 \circ best meet the criteria specified by a service participant; 1757 tools to appropriately track users of the descriptions and notify them when a new version 1758 0 1759 of the description is available.

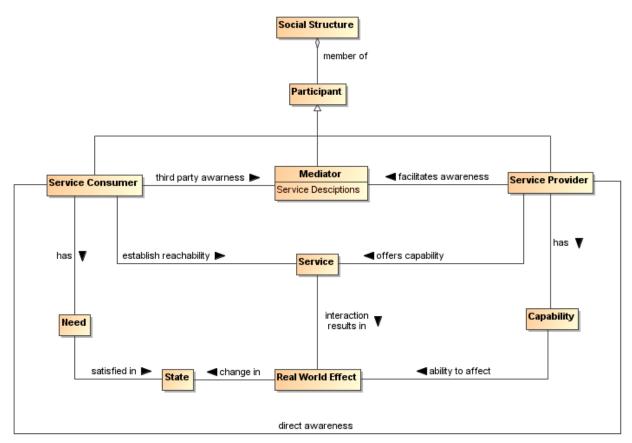

1760 **4.2 Service Visibility Model**

One of the key requirements for participants interacting with each other in the context of a SOA is
achieving visibility: before services can interoperate, the participants have to be visible to each other
using whatever means are appropriate. The Reference Model analyzes visibility in terms of awareness,
willingness, and reachability. In this section, we explore how visibility may be achieved.

1765 4.2.1 Visibility to Business

1766 The relationship of visibility to the SOA ecosystem encompasses both human social structures and automated IT mechanisms. Figure 21 depicts a business setting that is a basis for visibility as related to 1767 1768 the social structure Model in the Participation in a SOA Ecosystem view (see Section 3.1). Service 1769 consumers and service providers may have direct awareness or mediated awareness where mediated 1770 awareness is achieved through some third party. A consumer's willingness to use a service is reflected by 1771 the consumer's presumption of satisfying goals and needs based on the service description. Service 1772 providers offer capabilities that have real world effects that result in a change in state. Reachability of the 1773 service by the consumer may lead to interactions that change the state of the SOA ecosystem. The 1774 consumer can measure the change of state to determine if the claims made by description and the real 1775 world effects of consuming the service meet the consumer's needs.

1776

1779 Figure 21 - Visibility to Business

1780 Visibility and interoperability in a SOA ecosystem requires more than location and interface information.

1781 A meta-model for this broader view of visibility is depicted in Section 4.1. In addition to providing

1782 improved awareness of service capabilities through description of information such as reachability,

- behavior models, information models, functionality, and metrics, the service description may contain
 policies valuable for determination of willingness to interact.
- A mediator using service descriptions may provide event notifications to both consumers and providers
 about information relating to the descriptions. One example of this capability is a publish/subscribe model
- 1786 about mormation relating to the descriptions. One example of this capability is a publish/subscribe mode 1787 where the mediator allows consumers to subscribe to service description version changes made by the
- 1788 provider. Likewise, the mediator may provide notifications to the provider of consumers that have
- 1789 subscribed to service description updates.
- Another important capability in a SOA environment is the ability to narrow visibility to trusted members
 within a social structure. Mediators for awareness may provide policy based access to service
- 1792 descriptions allowing for the dynamic formation of awareness between trusted members.

1793 **4.2.2 Visibility**

Attaining visibility is described in terms of steps that lead to visibility. Different participant communities can bring different contexts for visibility within a single social structure, and the same general steps can

- 1796 be applied to each of the contexts to accomplish visibility.
- 1797 Attaining SOA visibility requires
- service description creation and maintenance,
- processes and mechanisms for achieving awareness of and accessing descriptions,
- processes and mechanisms for establishing willingness of participants,
- 1801 processes and mechanisms to determine reachability.

1802 Visibility may occur in stages, i.e. a participant can become aware enough to look or ask for further

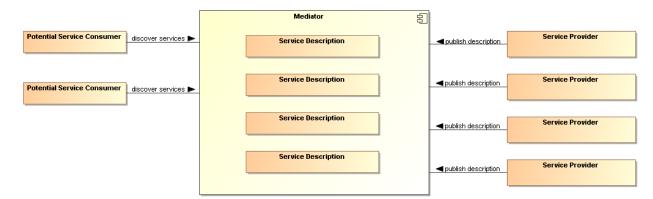

- 1803 description, and with this description, the participant can decide on willingness, possibly requiring
- additional description. For example, if a potential consumer has a need for a tree cutting (business)
- 1805 service, the consumer can use a web search engine to find web sites of providers. The web search
- 1806 engine (a mediator) gives the consumer links to relevant web pages and the consumer can access those 1807 descriptions. For those prospective providers that satisfy the consumer's criteria, the consumer's
- descriptions. For those prospective providers that satisfy the consumer's criteria, the consumer's
 willingness to interact increases. The consumer may contact several tree services to get detailed cost
- information (or arrange for an estimate) and may ask for references (further description). The consumer is
- likely to establish full visibility and proceed with interaction with the tree service who mutually establishes
- 1811 visibility.

1812 **4.2.2.1 Awareness**

- An important means for a service participant to be aware of another participant is to have access to a description of that participant and for the description to have sufficient completeness to establish the other requirements of visibility.
- 1816 Awareness is inherently a function of a participant; awareness can be established without any action on
- 1817 the part of the target participant other than the target providing appropriate descriptions. Awareness is
- 1818 often discussed in terms of consumer awareness of providers but the concepts are equally valid for 1819 provider awareness of consumers.
- 1820 Awareness can be decomposed into: creating the descriptions, making them available, and discovering
- the descriptions. Discovery can be initiated or it can be by notification. Initiated discovery for business
 may require formalization of the required capabilities and resources to achieve business goals.
- 1823 Achieving awareness in a SOA can range from word of mouth to formal service descriptions in a
- 1824 standards-based registry-repository. Some other examples of achieving awareness in a SOA are the
- 1825 use of a web page containing description information, email notifications of descriptions, and document 1826 based descriptions.
 - 1827 A mediator for awareness is a third party participant that provides awareness to one or more consumers
 - 1828 of one or more services. Direct awareness is awareness between a consumer and provider without the
 - use of a third party. A registry/repository can act as a mediator; a Web page displaying similar
 information can also be considered a mediator.
 - 1831 Direct awareness may be the result of having previously established an execution context, or direct
 - awareness may include determining the presence of services and then querying the service directly for
 - 1833 description. As an example, a priori visibility of some sensor device may provide the means for interaction
 - 1834 or a query for standardized sensor device metadata may be broadcast to multiple locations. If
 - acknowledged, the service interface for the device may directly provide description to a consumer so theconsumer can determine willingness to interact.
 - 1837 The same medium for awareness may be direct in one context and may be mediated in another context. 1838 For example, a service provider may maintain a web site with links to the provider's descriptions of
 - 1839 services giving the consumers direct awareness to the provider's services. Alternatively, a community
 - may maintain a mediated web site with links to various provider descriptions of services for any number of
 - 1841 consumers. More than one mediator may be involved, as different mediators may specialize in different
 - 1842 mediation functions.
 - 1843 Descriptions may be formal or informal. Section 4.1, provides a comprehensive model for service
 1844 description that can be used to mediate visibility. Using consistent description taxonomies and standards
 - 1845 based mediated awareness helps provide more effective awareness.

1846 4.2.2.1.1 Mediated Awareness

- 1847 Mediated awareness promotes loose coupling by keeping the consumers and services from explicitly
- 1848 referring to each other. Mediation lets interaction vary independently. Rather than all potential service
- 1849 consumers being informed on a continual basis about all services, there is a known or agreed upon
- 1850 facility or location that stores and supports discovery and/or notification related to the service description.

1864

1865

1852 Figure 22 - Mediated Service Awareness

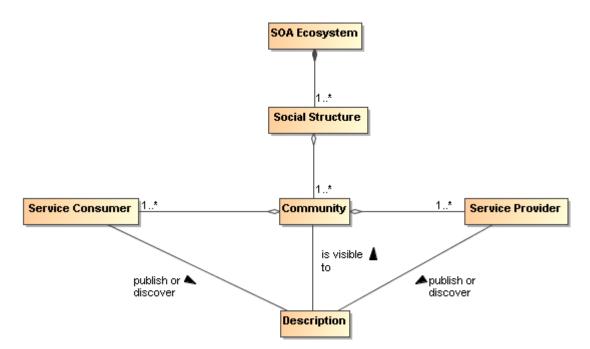

1853 In Figure 22, the potential service consumers perform queries or are notified in order to locate those 1854 services that satisfy their needs. As an example, the telephone book is a mediating registry where 1855 individuals perform manual searches to locate services (i.e. the yellow pages). The telephone book is 1856 also a mediated registry for solicitors to find and notify potential customers (i.e. the white pages).

In mediated service awareness for large and dynamic numbers of service consumers and service
 providers, the benefits of utilizing the mediator typically far outweigh the management issues associated
 with it. Some of the benefits of mediated service awareness are

- Potential service consumers have a known location for searching thereby eliminating needless and random searches
- Typically a consortium of interested parties (or a sufficiently large corporation) signs up to host
 the mediation facility
 - Standardized tools and methods can be developed and promulgated to promote interoperability and ease of use.
- 1866 However, mediated awareness can have some risks associated with it:
- A single point of failure. If the mediation service fails then a large number of service providers and consumers are potentially adversely affected.
- A single point of control. If the central mediation service is owned by, or controlled by, someone other than the service consumers and/or providers then the latter may be put at a competitive disadvantage based on policies of the discovery provider.
- A common mechanism for mediated awareness is a registry/repository. The registry stores links or
 pointers to service description artifacts. The repository in this example is the storage location for the
 service description artifacts. Service descriptions can be pushed (publish/subscribe for example) or pulled
- 1875 from the registry/repository mediator.
- 1876 Registries/repositories may be referred to as federated when supported functions, such as responding to 1877 discovery requests, are distributed across multiple registry/repository instances.

1878 4.2.2.1.2 Awareness in Complex Social Structures

- Awareness applies to one or more communities within one or more social structures where a community
 consists of at least one description provider and one description consumer. These communities may be
 part of the same social structure or be part of different ones.
- 1881 part of the same social structure of be part of different ones.
- In Figure 23, awareness can be between consumers and providers within a single community, multiple
 communities, or all communities in the social structure. The social structure can encourage or restrict
 awareness through its policies, and these policies can affect participant willingness. The information
- 1885 about policies should be incorporated in the relevant descriptions. The social structure also governs the
- 1886 conditions for establishing contracts, the results of which are reflected in the execution context if
- 1887 interaction is to proceed.

1889 Figure 23 - Awareness in a SOA Ecosystem

1890 IT policy/contract mechanisms can be used by visibility mechanisms to provide awareness between

1891 communities. The IT mechanisms for awareness may incorporate trust mechanisms to enable

awareness between trusted communities. For example, government organizations may want to limit
 awareness of an organization's services to specific communities of interest.

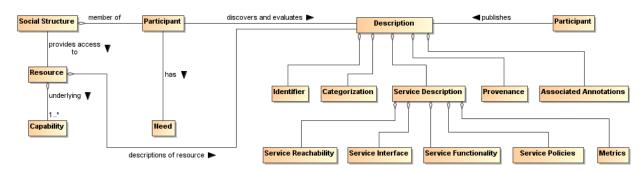

Another common business model for awareness is maximizing awareness to communities within the
social structure, the traditional market place business model. A centralized mediator often arises as a
provider for this global visibility, a gatekeeper of visibility so to speak. For example, Google is a
centralized mediator for accessing information on the web. As another example, television networks have
centralized entities providing a level of awareness to communities that otherwise could not be achieved
without going through the television network.

However, mediators have motivations, and they may be selective in which information they choose to
 make available to potential consumers. For example, in a secure environment, the mediator may enforce
 security policies and make information selectively available depending on the security clearance of the
 consumers.

1904 **4.2.2.2 Willingness**

Having achieved awareness, participants use descriptions to help determine their willingness to interact
 with another participant. Both awareness and willingness are determined prior to consumer/provider
 interaction.

- 1908
- 1909

1911

1912 Figure 24 - Business, Description and Willingness

1913 Figure 24 relates elements of the *Participation in a SOA Ecosystem* view, and elements from the Service

1914 Description Model to willingness. By having a willingness to interact within a particular social structure,

1915 the social structure provides the participant access to capabilities based on conditions the social structure

1916 finds appropriate for its context. The participant can use these capabilities to satisfy goals and objectives

1917 as specified by the participant's needs.

In Figure 24, information used to determine willingness is defined by Description. Information referenced
 by Description may come from many sources. For example, a mediator for descriptions may provide 3rd
 party annotations for reputation. Another source for reputation may be a participant's own history of
 interactions with another participant.

A participant inspects functionality for potential satisfaction of needs. Identity is associated with any
participant, however, identity may or may not be verified. If available, participant reputation may be a
deciding factor for willingness to interact. Policies and contracts referenced by the description may be
particularly important to determine the agreements and commitments required for business interactions.
Provenance may be used for verification of authenticity of a resource.

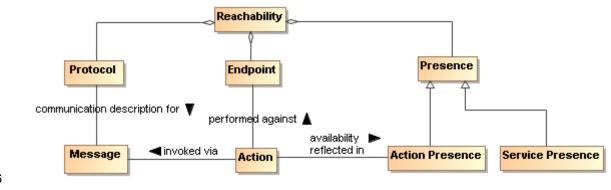

Mechanisms that aid in determining willingness make use of the artifacts referenced by descriptions of services. Mechanisms for establishing willingness could be as simple as rendering service description information for human consumption to automated evaluation of functionality, policies, and contracts by a rules engine. The rules engine for determining willingness could operate as a policy decision procedure

1931 as defined in Section 4.4.

1932 **4.2.2.3 Reachability**

1933 Reachability involves knowing the endpoint, protocol, and presence of a service. At a minimum,

reachability requires information about the location of the service and the protocol describing the means of communication.

1936

1937 Figure 25 - Service Reachability

1938 Endpoint

1939An endpoint is a reference-able entity, processor or resource against which an action can be1940performed.

1941 Protocol

1942

1944

A protocol is a structured means by which details of a service interaction mechanism are defined.

1943 Presence

Presence is the measurement of reachability of a service at a particular point in time.

A protocol defines a structured method of communication. Presence is determined by interaction through
a communication protocol. Presence may not be known in many cases until the interaction begins. To
overcome this problem, IT mechanisms may make use of presence protocols to provide the current
up/down status of a service.

Service reachability enables service participants to locate and interact with one another. Each action may have its own endpoint and also its own protocols associated with the endpoint and whether there is presence for the action through that endpoint. Presence of a service is an aggregation of the presence of the service's actions, and the service level may aggregate to some degraded or restricted presence if some action presence is not confirmed. For example, if error processing actions are not available, the service can still provide required functionality if no error processing is needed. This implies reachability relates to each action as well as applying to the service/business as a whole.

1956 **4.2.3 Architectural Implications**

1957 Visibility in a SOA ecosystem has the following architectural implications on mechanisms providing 1958 support for awareness, willingness, and reachability:

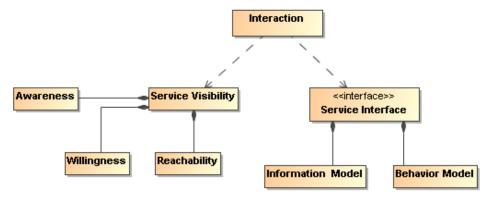

- 1959 Mechanisms providing support for awareness have the following minimum capabilities: 1960 creation of Description, preferably conforming to a standard Description format and 0 1961 structure: 1962 publishing of Description directly to a consumer or through a third party mediator: 0 discovery of Description, preferably conforming to a standard for Description discovery; 1963 0 notification of Description updates or notification of the addition of new and relevant 1964 0 Descriptions: 1965 1966 classification of Description elements according to standardized classification schemes. 0 In a SOA ecosystem with complex social structures, awareness may be provided for specific 1967 1968 communities of interest. The architectural mechanisms for providing awareness to communities 1969 of interest require support for: 1970 policies that allow dynamic formation of communities of interest; 0 1971 0 trust that awareness can be provided for and only for specific communities of interest, the bases of which is typically built on keying and encryption technology. 1972 The architectural mechanisms for determining willingness to interact require support for: 1973 verification of identity and credentials of the provider and/or consumer; 1974 0 1975 access to and understanding of description; 0 inspection of functionality and capabilities; 1976 0 inspection of policies and/or contracts. 1977 0 The architectural mechanisms for establishing reachability require support for: 1978 1979 the location or address of an endpoint; 0 1980 verification and use of a service interface by means of a communication protocol; 0
- 1981odetermination of presence with an endpoint which may only be determined at the point of1982interaction but may be further aided by the use of a presence protocol for which the1983endpoints actively participate.

4.3 Interacting with Services Model

1985 Interaction is the activity involved in using a service to access capability in order to achieve a particular 1986 desired real world effect, where real world effect is the actual result of using a service. An interaction can 1987 be characterized by a sequence of communicative actions. Consequently, interacting with a service, i.e. 1988 participating in joint action with the service—usually mediated by a series of message exchangesinvolves individual actions performed by both the service and the consumer.⁸ Note that a participant (or
 delegate acting on behalf of the participant) can be the sender of a message, the receiver of a message,
 or both.

1992 **4.3.1 Interaction Dependencies**

1993 Recall from the Reference Model that service visibility is the capacity for those with needs and those with capabilities to be able to interact with each other, and that the service interface is the means by which the 1994 underlying capabilities of a service are accessed. Ideally, the details of the underlying service 1995 1996 implementation are abstracted away by the service interface. [Service] interaction therefore has a direct 1997 dependency on the visibility of the service as well as its implementation-neutral interface (see Figure 26). 1998 Service visibility is composed of awareness, willingness, and reachability and service interface is 1999 composed of the information and behavior models. Service visibility is modeled in Section 4.2 while service interface is modeled in Section 4.1. 2000

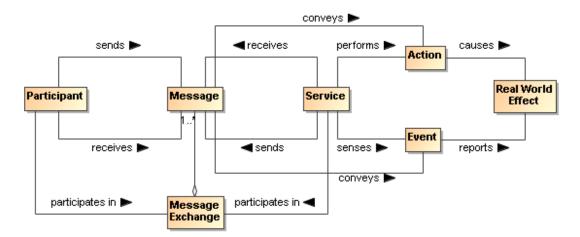

2001

2002 Figure 26 - Interaction dependencies

2003 4.3.2 Actions and Events

The SOA-RAF uses message exchange between service participants to denote actions performed against and by the service, and to denote events that report on real world effects that are caused by the service actions. A visual model of the relationship between these concepts is shown in Figure 27.

⁸ In order for multiple actors to participate in a joint action, they must each act according to their role within the joint action. For SOA-based systems, this is achieved through a message exchange style of communication. The concept of "joint action" is further described in Section **Error! Reference source not found.**

2008 Figure 27 - A "message" denotes either an action or an event

Both actions and events, realized by the SOA services, are denoted by the messages. The Reference Model states that the action model characterizes the "permissible set of actions that may be invoked against a service." We extend that notion here to include events as part of the event model and that messages are intended for invoking actions or for notification of events.

2013 In Section 3.2.3 we saw that participants interact with each other in order to participate in joint actions. A

2014 joint action is not itself the same thing as the result of the joint action. When a joint action is participated in

with a service, the real world effect that results may be reported in the form of an event notification.

2016 **4.3.3 Message Exchange**

2017 Message exchange is the means by which service participants (or their delegates) interact with each

2018 other. There are two primary modes of interaction: joint actions that cause real world effects and 2019 notification of events that report real world effects.⁹

A message exchange is used to affect an action when the messages contain the appropriately formatted content, are directed towards a particular action in accordance with the action model, and the delegates involved interpret the message appropriately.

A message exchange is also used to communicate event notifications. An event is an occurrence that is of interest to some participant; in our case when some real world effect has occurred. Just as action messages have formatting requirements, so do event notification messages. In this way, the Information Model of a service must specify the syntax (structure), and semantics (meaning) of the action messages and event notification messages as part of a service interface. It must also specify the syntax and semantics of any data that is carried as part of a payload of the action or event notification message. The Information Model is described in greater detail in the Service Description Model (see Section 4.1).

In addition to the Information Model that describes the syntax and semantics of the messages and data
 payloads, exception conditions and error handling in the event of faults (e.g., network outages, improper
 message formats, etc.) must be specified or referenced as part of the Service Description.

⁹ The notion of "joint" in joint action implies that you have to have a speaker and a listener in order to interact.

- 2033 When a message is used to invoke an action, the correct interpretation typically requires the receiver to
- perform an operation, which itself invokes a set of private, internal actions. These operations represent
 the sequence of (private) actions a service must perform in order to validly participate in a given joint
 action.
- Similarly, the correct consequence of realizing a real world effect may be to initiate the reporting of that real world effect via an event notification.

2039 Message Exchange

2040 The means by which joint action and event notifications are coordinated by service participants 2041 (or delegates).

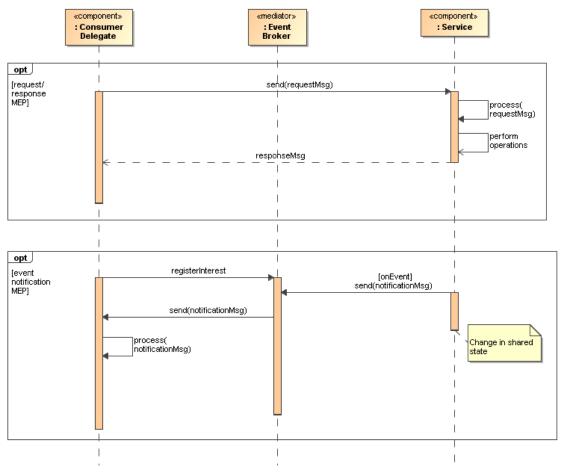

2042 **Operations**

2043 The sequence of actions a service must perform in order to validly participate in a given joint action.

2045 4.3.3.1 Message Exchange Patterns (MEPs)

- 2046 The basic temporal aspect of service interaction can be characterized by two fundamental message 2047 exchange patterns (MEPs):
- Request/response to represent how actions cause a real world effect
- Event notification to represent how events report a real world effect

This is by no means a complete list of all possible MEPs used for inter- or intra-enterprise messaging but it does represent those that are most commonly used in exchange of information and reporting changes in state both within organizations and across organizational boundaries.

2053 2054

4 Figure 28 - Fundamental SOA message exchange patterns (MEPs)

- 2055 Recall from the Reference Model that the Process Model characterizes "the temporal relationships 2056 between and temporal properties of actions and events associated with interacting with the service."
- Thus, MEPs are a key element of the Process Model. The meta-level aspects of the Process Model (just as with the Action Model) are provided as part of the Service Description Model (see Section 4.1).

2059 In the UML sequence diagram shown in Figure 28 it is assumed that the service participants (consumer 2060 and provider) have delegated message handling to hardware or software delegates acting on their behalf. 2061 In the case of the service consumer, this is represented by the Consumer Delegate component. In the case of the service provider, the delegate is represented by the Service component. The message 2062 interchange model illustrated represents a logical view of the MEPs and not a physical view. In other 2063 2064 words, specific hosts, network protocols, and underlying messaging system are not shown as these tend 2065 to be implementation specific. Although such implementation-specific elements are considered outside 2066 the scope of this document, they are important considerations in modeling the SOA execution context. 2067 Recall from the Reference Model that the execution context of a service interaction is "the set of 2068 infrastructure elements, process entities, policy assertions and agreements that are identified as part of an instantiated service interaction, and thus forms a path between those with needs and those with 2069 2070 capabilities."

2071 4.3.3.2 Request/Response MEP

In a request/response MEP, the Consumer Delegate component sends a request message to the Service component. The Service component then processes the request message. Based on the content of the message, the Service component performs the service operation and the associated private actions.
Following the completion of these operations, a response message is returned to the Consumer Delegate component. The response could be that a step in a process is complete, the initiation of a follow-on operation, or the return of requested information.¹⁰

Although the sequence diagram shows a *synchronous* interaction (because the sender of the request message, i.e., Consumer Delegate, is blocked from continued processing until a response is returned from the Service) other variations of request/response are valid, including *asynchronous* (non-blocking) interaction through use of queues, channels, or other messaging techniques.

2082 What is important to convey here is that the request/response MEP represents action, which causes a 2083 real world effect, irrespective of the underlying messaging techniques and messaging infrastructure used 2084 to implement the request/response MEP.

2085 4.3.3.3 Event Notification MEP

An event is made visible to interested consumers by means of an event notification message exchange that reports a real world effect; specifically, a change in shared state between service participants. The basic event notification MEP takes the form of a one-way message sent by a notifier component (in this case, the Service component) and received by components with an interest in the event (here, the Consumer Delegate component).

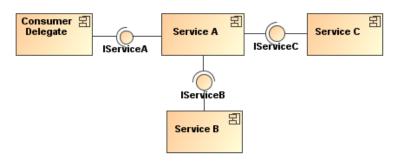

2091 Often the sending component may not be fully aware of all the components that wish to receive the 2092 notification; particularly in so-called publish/subscribe ("pub/sub") situations. In event notification

¹⁰ There are cases when a response is not always desired and this would be an example of a "one-way" MEP. Similarly, while not shown here, there are cases when some type of "callback" MEP is required in which the consumer agent is actually exposed as a service itself and is able to process incoming messages from another service.

- 2093 message exchanges, it is rare to have a tightly-coupled link between the sending and the receiving 2094 component(s) for a number of practical reasons. One of the most common needs for pub/sub messaging 2095 is the potential for network outages or communication interrupts that can result in loss of notification of 2096 events. Therefore, a third-party mediator component is often used to decouple the sending and receiving 2097 components.
- Although this is typically an implementation issue, because this type of third-party decoupling is so common in event-driven systems, it is warranted for use in modeling this type of message exchange in
- 2100 the SOA-RAF. This third-party intermediary is shown in Figure 28 as an Event Broker mediator. As with
- 2101 the request/response MEP, no distinction is made between synchronous versus asynchronous
- 2102 communication, although asynchronous message exchange is illustrated in the UML sequence diagram
- 2103 depicted in Figure 28.

2104 4.3.4 Composition of Services

2105 Composition of services is the act of aggregating or "composing" a single service from one or more other 2106 services. A simple model of service composition is illustrated in Figure 29.

2107

- 2108 Figure 29 Simple model of service composition
- Here, Service A is a service that has an exposed interface IServiceA, which is available to the Consumer
 Delegate and relies on two other services in its implementation. The Consumer Delegate does not know
 that Services B and C are used by Service A, or whether they are used in serial or parallel, or if their
 operations succeed or fail. The Consumer Delegate only cares about the success or failure of Service A.
 The exposed interfaces of Services B and C (IService B and IServiceC) are not necessarily hidden from
 the Consumer Delegate; only the fact that these services are used as part of the composition of Service
- A. In this example, there is no practical reason the Consumer Delegate could not interact with Service B or Service C in some other interaction scenario.
- 2117 It is possible for a service composition to be opaque from one perspective and transparent from another.
- 2118 For example, a service may appear to be a single service from the Consumer's Delegate's perspective,
- 2119 but is transparently composed of one or more services from a service management perspective. A
- 2120 Service Management capability needs to be able to have visibility into the composition in order to properly
- 2121 manage the dependencies between the services used in constructing the composite service—including
- 2122 managing the service's lifecycle. The subject of services as management entities is described and
- modeled in the *Ownership in a SOA Ecosystem* View of the SOA-RAF and is not further elaborated in this section. The point to be made here is that there can be different levels of opaqueness or transparency
- 2125 when it comes to visibility of service composition.
- Services can be composed in a variety of ways including direct consumer-to-service interaction by using programming techniques, or they can be aggregated by means of an aggregation engine approach that leverages a service composition scripting language. Such approaches are further elaborated in the
- 2129 following sub-sections on service-oriented business processes and collaborations.

2130 4.3.4.1 Service-Oriented Business Processes

- 2131 The concepts of business processes and collaborations in the context of transactions and exchanges
- 2132 across organizational boundaries are described and modeled as part of the Participation in a SOA
- *Ecosystem* view of this reference architecture (see Section 3). Here, we focus on the belief that the principle of composition of services can be applied to business processes and collaborations. Of course,

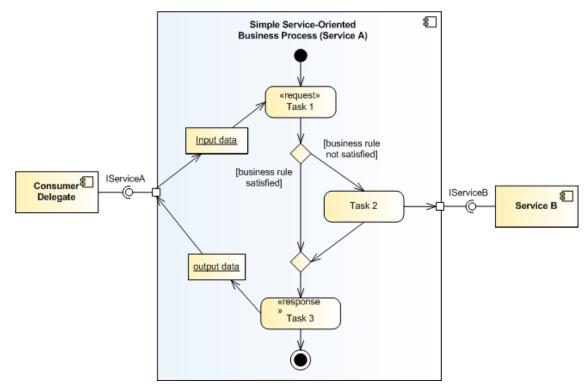

- 2135 business processes and collaborations traditionally represent complex, multi-step business functions that
- 2136 may involve multiple participants, including internal users, external customers, and trading partners.
- 2137 Therefore, such complexities cannot simply be ignored when transforming traditional business processes
- and collaborations to their service-oriented variants.

2139 Business Processes

- 2140Business processes are a set of one or more linked activities that are performed to achieve a
certain business outcome.
- Service orientation as applied to business processes (i.e., "service-oriented business processes") means
 that the aggregation or composition of all of the abstracted activities, flows, and rules that govern a
 business process can themselves be abstracted as a service [BLOOMBERG/SCHMELZER].
- 2145 When business processes are abstracted in this manner and accessed through SOA services, all of the 2146 concepts used to describe and model composition of services that were articulated in Section 4.3.4 apply. 2147 There are some important differences between a composite service that represents an abstraction of a 2148 business process and a composite service that represents a single-step business interaction. Business 2149 processes have temporal properties and can range from short-lived processes that execute on the order of minutes or hours to long-lived processes that can execute for weeks, months, or even years. Further, 2150 2151 these processes may involve many participants. These are important considerations for the consumer of a service-oriented business process and these temporal properties must be articulated as part of the 2152 2153 meta-level aspects of the service-oriented business process in its Service Description, along with the 2154 meta-level aspects of any sub-processes that may be of use or need to be visible to the service
- 2155 consumer.
- 2156 In addition, a workflow activity represents a unit of work that some actor acting in a described role (i.e.,
- 2157 role player) is asked to perform. Activities can be broken down into steps with each step representing a 2158 task for the role player to perform. A technique that is used to compose service-oriented business
- task for the role player to perform. A technique that is used to compose service-oriented business processes that are hierarchical (top-down) and self-contained in nature is known as *orchestration*.

2160 Orchestration

- 2161A technique used to compose service-oriented business processes that are executed and2162coordinated by an actor acting as "conductor."
- 2163 An orchestration is typically implemented using a scripting approach to compose service-oriented
- business processes. This typically involves use of a standards-based orchestration scripting language.
- 2165 In terms of automation, an orchestration can be mechanized using a business process orchestration
- engine, which is a hardware or software component (delegate) responsible for acting in the role of central
- 2167 conductor/coordinator responsible for executing the flows that comprise the orchestration.
- A simple generic example of such an orchestration is illustrated in Figure 30.

2170 Figure 30 - Abstract example of orchestration of service-oriented business process

Here, we use a UML activity diagram to model the simple service-oriented business process as it allows

2172 us to capture the major elements of business processes such as the set of related tasks to be performed,

2173 linking between tasks in a logical flow, data that is passed between tasks, and any relevant business

rules that govern the transitions between tasks. A task is a unit of work that an individual, system, or

2175 organization performs and can be accomplished in one or more steps or subtasks. While subtasks can

be readily modeled, they are not illustrated in the orchestration model in Figure 30.

This particular example is based on a request/response MEP and captures how one particular task (Task
actually utilizes an externally-provided service, Service B. The entire service-oriented business

2179 process is exposed as Service A that is accessible via its externally visible interface, IServiceA.

2180 Although not explicitly shown in the orchestration model above, it is assumed that there exists a software

2181 or hardware component, i.e., orchestration engine that executes the process flow. Recall that a central

concept to orchestration is that process flow is coordinated and executed by a single conductor delegate;
hence the name "orchestration."

2184 4.3.4.2 Service-Oriented Business Collaborations

- 2185 Business collaborations typically represent the interaction involved in executing business transactions.
- 2186 It is important to note that business collaborations represent "peer"-style interactions; in other words,
- 2187 peers in a business collaboration act as equals. This means that unlike the orchestration of business
- 2188 processes, there is no single or central entity that coordinates or "conducts" a business collaboration.
- 2189 These peer styles of interactions typically occur between trading partners that span organizational 2190 boundaries.
- 2191 Business collaborations can also be service-enabled. For purposes of this Reference Architecture
- 2192 Foundation, we refer to these as "service-oriented business collaborations." Service-oriented business
- 2193 collaborations do not necessarily imply exposing the entire peer-style business collaboration as a service
- 2194 itself but rather the collaboration uses service-based interchanges.
- 2195 The technique that is used to compose service-oriented business collaborations in which multiple parties 2196 collaborate in a peer-style as part of some larger business transaction by exchanging messages with

2197 trading partners and external organizations (e.g., suppliers) is known as *choreography*

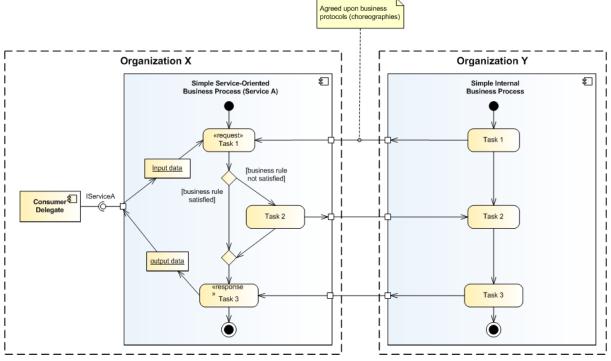

2198 [NEWCOMER/LOMOW].

2199 Choreography

A technique used to characterize service-oriented business collaborations based on ordered message exchanges between peer entities in order to achieve a common business goal.

Choreography differs from orchestration primarily in that each party in a business collaboration describes its part in the service interaction. Note that choreography as we have defined it here should not be confused with the term *process choreography*, which is defined in the *Participation in a SOA Ecosystem* view as "the description of the possible interactions that may take place between two or more participants to fulfill an objective." This is an example of domain-specific nomenclature that often leads to confusion and why we are making note of it here.

A simple generic example of a choreography is illustrated in Figure 31.

2209

2210 Figure 31 - Abstract example of choreography of service-oriented business collaboration

This example, which is a variant of the orchestration example illustrated earlier in Figure 30 adds trust boundaries between two organizations; namely, Organization X and Organization Y. It is assumed that these two organizations are peer entities that have an interest in a business collaboration, for example, Organization X and Organization Y could be trading partners. Organization X retains the service-oriented business process Service A, which is exposed to internal consumers via its provided service interface,

IServiceA. Organization Y also has a business process that is involved in the business collaboration; however, for this example, it is an internal business process that is not exposed to potential consumers

2218 either within or outside its organizational boundary.

2219 The scripting language that is used for the choreography needs to define how and when to pass control

from one trading partner to another, i.e., between Organization X and Organization Y. Defining the business protocols used in the business collaboration involves precisely specifying the visible message

exchange behavior of each of the parties involved in the protocol, without revealing internal implementation details [NEWCOMER/LOMOW].

In a peer-style business collaboration, a choreography scripting language must be capable of describing the coordination of those service-oriented processes that cross organizational boundaries.

4.3.5 Architectural Implications of Interacting with Services

Interacting with Services has the following architectural implications on mechanisms that facilitate serviceinteraction:

• A well-defined service Information Model that:

2230		0	describes the syntax and semantics of the messages used to denote actions and events;
2231		0	describes the syntax and semantics of the data payload(s) contained within messages;
2232		0	documents exception conditions in the event of faults due to network outages, improper
2233			message/data formats, etc.;
2234		0	is both human readable and machine processable;
2235		0	is referenceable from the Service Description artifact.
2236	•	A well-define	ed service Behavior Model that:
2237		0	characterizes the knowledge of the actions invokes against the service and events that
2238			report real world effects as a result of those actions;
2239		0	characterizes the temporal relationships and temporal properties of actions and events
2240		-	associated in a service interaction;
2241		0	describe activities involved in a workflow activity that represents a unit of work;
2242		0	describes the role (s) that a role player performs in a service-oriented business process
2243		-	or service-oriented business collaboration;
2244		0	is both human readable and machine processable;
2245		0	is referenceable from the Service Description artifact.
2246	•		position mechanisms to support orchestration of service-oriented business processes and
2247			ny of service-oriented business collaborations such as:
2248		o	Declarative and programmatic compositional languages;
2249		0	Orchestration and/or choreography engines that support multi-step processes as part of a
2250		-	short-lived or long-lived business transaction;
2251		0	Orchestration and/or choreography engines that support compensating transactions in
2252		-	the presences of exception and fault conditions.
2253	•	Infrastructur	e services that provides mechanisms to support service interaction, including but not
2254		limited to:	
2255		0	mediation services such as message and event brokers, providers, and/or buses that
2256		-	provide message translation/transformation, gateway capability, message persistence,
2257			reliable message delivery, and/or intelligent routing semantics;
2258		0	binding services that support translation and transformation of multiple application-level
2259			protocols to standard network transport protocols;
2260		0	auditing and logging services that provide a data store and mechanism to record
2261			information related to service interaction activity such as message traffic patterns,
2262			security violations, and service contract and policy violations
2263		0	security services that provide centralized authorization and authentication support, etc.,
2264			which provide protection against common security threats in a SOA ecosystem;
2265		0	monitoring services such as hardware and software mechanisms that both monitor the
2266			performance of systems that host services and network traffic during service interaction,
2267			and are capable of generating regular monitoring reports.
2268	•	A lavered an	nd tiered service component architecture that supports multiple message exchange
2269			EPs) in order to:
2270		0	promote the industry best practice of separation of concerns that facilitates flexibility in
2271			the presence of changing business requirements;
2272		0	promote the industry best practice of separation of roles in a service development
2273			lifecycle such that subject matter experts and teams are structured along areas of
2274			expertise;
2275		0	support numerous standard interaction patterns, peer-to-peer interaction patterns,
2276			enterprise integration patterns, and business-to-business integration patterns.

2277 4.4 Policies and Contracts Model

A common phenomenon of many machines and systems is that the scope of potential behavior is much broader than is actually needed for a particular circumstance. This is especially true of a system as powerful as a SOA ecosystem. As a result, the behavior and performance of the system tend to be under-constrained by the implementation; instead, the actual behavior is expressed by means of policies of some form. Policies define the choices that stakeholders make; these choices are used to guide the actual behavior of the system to the desired behavior and performance.

As noted in Section 3.1.5, a policy is a constraint of some form that is promulgated by a stakeholder who has the responsibility of ensuring that the constraint is enforced. In contrast, contracts are **agreements** between participants. However, like policies, it is a necessary part of contracts that they are enforceable.

2287 While responsibility for enforcement may differ, both contracts and policies share a common characteristic

- 2288 there is a **constraint** that must be enforced. In both cases the mechanisms needed to enforce
- constraints are likely to be identical; in this model we focus on the issues involved in representing policies and contracts and on some of the principles behind their enforcement.

2291 4.4.1 Policy and Contract Representation

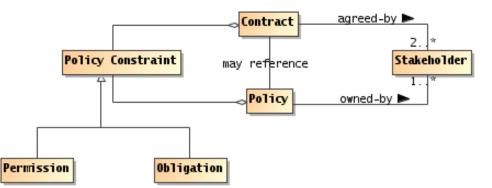

A **policy constraint** is a specific kind of constraint: the ontology of policies and contracts includes the core concepts of permission, obligation, owner, subject. In addition, it may be necessary to be able combine policy constraints and to be able to resolve policy conflicts.

2295 4.4.1.1 Policy Framework

2296 Policy Framework

A policy framework is a language in which policy constraints may be expressed.

A policy framework combines a syntax for expressing policy constraints together with a decision procedure for determining if a policy constraint is satisfied.

2300

2301 Figure 32 - Policies and Contracts

We can characterize (caricature) a policy framework in terms of a logical framework and an ontology of policies. The policy ontology details specific kinds of policy constraints that can be expressed; and the logical framework is a 'glue' that allows us to express combinations of policies.

2305 Logical Framework

A logical framework is a linguistic framework consisting of a syntax – a way of writing expressions - and a semantics – a way of interpreting the expressions.

2308 Policy Ontology

A policy ontology is a formalization of a set of concepts that are relevant to forming policy expressions.

- 2311 For example, a policy ontology that allows to identify simple constraints such as the existence of a
- property, or that a value of a property should be compared to a fixed value is often enough to express
 many basic constraints.
- Included in many policy ontologies are the basic signals of permissions and obligations. Some policy
 frameworks are sufficiently constrained that there is not possibility of representing an obligation; in which
- 2316 case there is often no need to 'call out' the distinction between permissions and obligations.
- The logical framework is also a strong determiner of the expressivity of the policy framework: the richer the logical framework, the richer the set of policy constraints that can be expressed. However, there is a strong inverse correlation between expressivity and ease and efficiency of implementation.
- 2320 In the discussion that follows we assume the following basic policy ontology:
- 2321 Policy Owner
- A policy owner is a stakeholder that asserts and enforces the policy.
- 2323 Policy Subject

2324

- A policy subject is an actor who is subject to the constraints of a policy or contract.
- 2325 Policy Constraint
- A policy constraint is a measurable and enforceable proposition that characterizes the constraint that the policy is about.
- 2328 Policy Object
- A policy object is an identifiable state, action or resource that is potentially constrained by the policy.

2331 4.4.2 Policy and Contract Enforcement

The enforcement of policy constraints has to address two core problems: how to enforce the atomic policy
constraints, and how to enforce combinations of policy constraints. In addition, it is necessary to address
the resolution of policy conflicts.

2335 4.4.2.1 Enforcing Simple Policy Constraints

- The two primary kinds of policy constraint permission and obligation naturally lead to different styles
 of enforcement. A permission constraint must typically be enforced *prior* to the policy subject invoking the
 policy object. On the hand, an obligation constraint must typically be enforced post-facto through some
 form of auditing process and remedial action.
- For example, if a communications policy required that all communication be encrypted, this is enforceable at the point of communication: any attempt to communicate a message that is not encrypted can be blocked.
- Similarly, an obligation to pay for services rendered is enforced by ensuring that payment arrives within a reasonable period of time. Invoices are monitored for prompt (or lack of) payment.
- The key concepts in enforcing both forms of policy constraint are the policy decision and the policy enforcement.
- 2347 Policy Decision

2348

- A policy decision is a determination as to whether a given policy constraint is satisfied or not.
- A policy decision is effectively a measurement of some state typically a portion of the SOA ecosystem's shared state. This implies a certain *timeliness* in the measuring: a measurement that is too early or is too late does not actually help in determining if the policy constraint is satisfied appropriately.

2352 Policy Enforcement

- A policy enforcement is the use of a mechanism which limits the behavior and/or state of policy subjects to comply with a policy decision.
- A policy enforcement implies the use of some mechanism to ensure compliance with a policy decision.
 The range of mechanisms is completely dependent on the kinds of atomic policy constraints that the

2357 policy framework may support. As noted above, the two primary styles of constraint - permission and 2358 obligation -lead to different styles of enforcement.

2359 4.4.2.2 Conflict Resolution

2360 Whenever it is possible that more than one policy constraint applies in a given situation, there is the 2361 potential that the policy constraints themselves are not mutually consistent. For example, a policy 2362 constraint that requires communication to be encrypted and a policy constraint that requires an 2363 administrator to read every communication conflict with each other - the two policy constraints cannot both be satisfied concurrently. 2364

2365 In general, with sufficiently rich policy frameworks, it is not possible to always resolve policy conflicts 2366 automatically. However, a reasonable approach is to augment the policy decision process with simple policy conflict resolution rules; with the potential for escalating a policy conflict to human adjudication. 2367

2368 **Policy Conflict**

2384

2385

2386

2387

2388

2389

2390

2391

2392

2394

2395

2396

2397

2398 2399

2400

2401

2402

2403

2404

2405

2369 A policy conflict exists between two or more policy constraints in a policy decision process if the satisfaction of one or more policy constraints leads directly to the violation of one or more other 2370 policy constraints. 2371

2372 **Policy Conflict Resolution**

2373 A policy conflict resolution rule is a way of determining which policy constraints should prevail if a 2374 policy conflict occurs.

2375 The inevitable consequence of policy conflicts is that it is not possible to guarantee that all policy 2376 constraints are satisfied at all times. This, in turn, implies a certain *flexibility* in the application of policy 2377 constraints: each individual constraint may not always be honored.

4.4.3 Architectural Implications 2378

- 2379 The key choices that must be made in a system of policies center on the policy framework, policy enforcement, and conflict resolution 2380
- 2381 There SHOULD be a standard policy framework that is adopted across ownership domains within the • 2382 SOA ecosystem: 2383
 - This framework MUST permit the expression of simple policy constraints 0
 - The framework MAY allow (to a varying extent) the combination of policy constraints, 0 including
 - Both positive and negative constraints •
 - Conjunctions and disjunctions of constraints •
 - The quantification of constraints
 - The framework MUST at least allow the policy subject and the policy object to be identified as 0 well as the policy constraint.
 - The framework MAY allow further structuring of policies into modules, inheritance between 0 policies and so on.
- 2393 There SHOULD be mechanisms that facilitate the application of policies:
 - There SHOULD be mechanisms that allow policy decisions to be made, consistent with the \circ policy frameworks.
 - There SHOULD be mechanisms to enforce policy decisions 0
 - There SHOULD be mechanisms to support the measurement of whether certain policy constraints are satisfied or not, or to what degree they are satisfied.
 - Such enforcement mechanisms MAY include support for both permission-style • constraints and obligation-style constraints.
 - Enforcement mechanisms MAY support the simultaneous enforcement of multiple policy constraints across multiple points in the SOA ecosystem.
 - There SHOULD be mechanisms to resolve policy conflicts 0
 - This MAY involve escalating policy conflicts to human adjudication.
 - There SHOULD be mechanisms that support the management and promulgation of policies.

5 Ownership in a SOA Ecosystem View

- 2407
- 2408 2409
- 2409

Governments are instituted among Men, deriving their just power from the consent of the governed American Declaration of Independence

The *Ownership in a SOA Ecosystem* View focuses on the issues, requirements and responsibilities
 involved in owning a SOA-based system.

2413 Ownership of a SOA-based system in a SOA ecosystem raises significantly different challenges to

2414 owning other complex systems – such as Enterprise suites – because there are strong limits on the 2415 control and <u>authority</u> of any one party when a system spans multiple ownership domains.

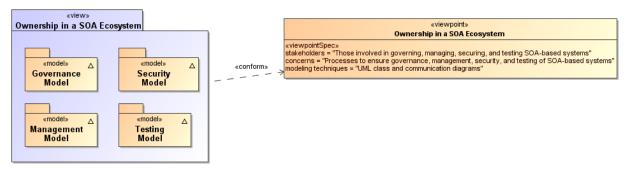

Even when a SOA-based system is deployed internally within an organization, there are multiple internal

2417 stakeholders involved and there may not be a simple hierarchy of control and management. Thus, an

2418 early consideration of how multiple boundaries affect SOA-based systems provides a firm foundation for

2419 dealing with them in whatever form they are found rather than debating whether the boundaries should

- 2420 exist.
- 2421 This view focuses on the governance and management of SOA-based systems, on the security
- challenges involved in running a SOA-based system, and testing challenges.

2423

2424 Figure 33 - Model Elements Described in the Ownership in a SOA Ecosystem View

2425 The following subsections present models of these functions.

2426 **5.1 Governance Model**

The Reference Model defines Service Oriented Architecture as an architectural paradigm for organizing and utilizing distributed capabilities that may be under the control of different ownership domains [SOA-RM]. Consequently, it is important that organizations that plan to engage in service interactions adopt governance policies and procedures sufficient to ensure that there is standardization across both internal and external organizational boundaries to promote the effective creation and use of SOA-based services.

2432 **5.1.1 Understanding Governance**

2433 5.1.1.1 Terminology

Governance is about making decisions that are aligned with the overall organizational strategy and
 culture of the enterprise. [Gartner] It specifies the decision rights and accountability framework to
 encourage desirable behaviors [Weill/Ross-MIT Sloan School] towards realizing the strategy and
 defines incentives (positive or negative) towards that end. It is less about overt control and strict
 adherence to rules, and more about guidance and effective and equitable usage of resources to ensure
 sustainability of an organization's strategic objectives. [TOGAF v8.1]

- To accomplish this, governance requires organizational structure and processes and must identify who has authority to define and carry out its mandates. It must address the following questions:
- 2442 1. what decisions must be made to ensure effective management and use?,
- 2443 2. who should make these decisions?,
- 2444 3. how will these decisions be made and monitored? , and
- 2445 4. how will these decisions be communicated?
- 2446 The intent is to achieve goals, add value, and reduce risk.

Within a single ownership domain such as an enterprise, generally there is a hierarchy of governance
structures. Some of the more common enterprise governance structures include corporate governance,
technology governance, IT governance, and architecture governance [TOGAF v8.1]. These governance
structures can exist at multiple levels (global, regional, and local) within the overall enterprise.

It is often asserted that SOA governance is a specialization of IT governance as there is a natural hierarchy of these types of governance structures; however, the focus of SOA governance is less on decisions to ensure effective management and use of IT as it is to ensure effective management and use of SOA-based systems. Certainly, SOA governance must still answer the basic questions also associated with IT governance, i.e., who should make the decisions, and how these decisions will be made and monitored.

2457 **5.1.1.2 Relationship to Management**

There is often confusion centered on the relationship between governance and management. As 2458 described earlier, governance is concerned with decision making. Management, on the other hand, is 2459 concerned with execution. Put another way, governance describes the world as leadership wants it to be; 2460 2461 management executes activities that intends to make the leadership's desired world a reality. Where 2462 governance determines who has the authority and responsibility for making decisions and the 2463 establishment of guidelines for how those decisions should be made, management is the actual process 2464 of making, implementing, and measuring the impact of those decisions [Loeb]. Consequently, 2465 governance and management work in concert to ensure a well-balanced and functioning organization as 2466 well as an ecosystem of inter-related organizations. In the sections that follow, we elaborate further on 2467 the relationship between governance and management in terms of setting and enforcing service policies, 2468 contracts, and standards as well as addressing issues surrounding regulatory compliance.

2469 **5.1.1.3 Why is SOA Governance Important?**

One of the hallmarks of SOA that distinguishes it from other architectural paradigms for distributed
computing is the ability to provide a uniform means to offer, discover, interact with and use capabilities
(as well the ability to compose new capabilities from existing ones) all in an environment that transcends
domains of ownership. Consequently, ownership, and issues surrounding it, such as obtaining
acceptable terms and conditions (T&Cs) in a contract, is one of the primary topics for SOA governance.
Generally, IT governance does not include T&Cs, for example, as a condition of use as its primary
concern.

Just as other architectural paradigms, technologies, and approaches to IT are subject to change and
 evolution, so too is SOA. Setting policies that allow change management and evolution, establishing
 strategies for change, resolving disputes that arise, and ensuring that SOA-based systems continue to

fulfill the goals of the business are all reasons why governance is important to SOA.

2481 **5.1.1.4 Governance Stakeholders and Concerns**

As noted in Section 3.1.1 the participants in a service interaction include the service provider, the service consumer, and other interested or unintentional third parties. Depending on the circumstances, it may also include the owners of the underlying capabilities that the SOA services access. Governance must establish the policies and rules under which duties and responsibilities are defined and the expectations of participants are grounded. The expectations include transparency in aspects where transparency is mandated, trust in the impartial and consistent application of governance, and assurance of reliable and robust behavior throughout the SOA ecosystem.

2489 5.1.2 A Generic Model for Governance

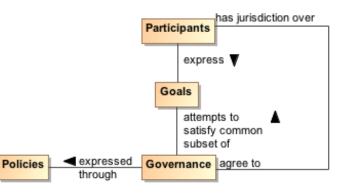

2490 Governance

2491Governance is the prescribing of conditions and constraints consistent with satisfying common2492goals and the structures and processes needed to define and respond to actions taken towards2493realizing those goals.

The following is a generic model of governance represented by segmented models that begin with motivation and proceed through measuring compliance. It is not all-encompassing but a focused subset that captures the aspects necessary to describe governance for SOA. It does not imply that practical application of governance is a single, isolated instance of these models; in reality, there may be hierarchical and parallel chains of governance that deal with different aspects or focus on different goals. This is discussed further in section 5.1.2.5. The defined models are simultaneously applicable to each of the overlapping instances.

A given enterprise may already have portions of these models in place. To a large extent, the models shown here are not specific to SOA; discussions on direct applicability begin in section 5.1.3.

2503 **5.1.2.1 Motivating Governance**

2504

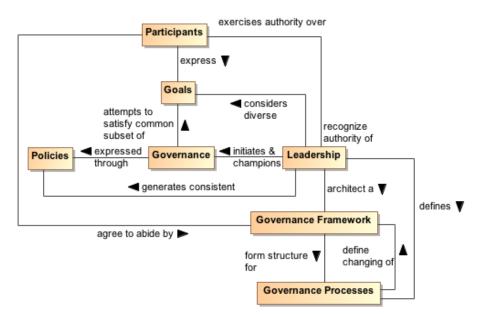

2505 Figure 34 - Motivating Governance

An organizational domain such as an enterprise is made up of participants who may be individuals or groups of individuals forming smaller organizational units within the enterprise. The overall business strategy should be consistent with the Goals of the participants; otherwise, the business strategy would not provide value to the participants and governance towards those ends becomes difficult if not impossible. This is not to say that an instance of governance simultaneously satisfies all the goals of all the participants; rather, the goals of any governance instance must sufficiently satisfy a useful subset of each participant's goals so as to provide value and ensure the cooperation of all the participants.

- A policy is the formal characterization of the conditions and constraints that governance deems as necessary to realize the goals which it is attempting to satisfy. Policy may identify required conditions or actions or may prescribe limitations or other constraints on permitted conditions or actions. For example, a policy may prescribe that safeguards must be in place to prevent unauthorized access to sensitive material. It may also prohibit use of computers for activities unrelated to the specified work assignment.
- 2518 Policy is made operational through the promulgation and implemention of Rules and Regulations (as
- 2519 defined in section 5.1.2.3).
- As noted in section 4.4.2, policy may be asserted by any participant or on behalf of the participant by its organization. Part of the purpose of governance is to arbitrate among diverse goals of participants and the diverse policies articulated to realize those goals. The intent is to form a consistent whole that allows governance to minimize ambiguity about its purpose. While resolving all ambiguity would be an ideal, it is unlikely that all inconsistencies will be identified and resolved before governance becomes operational.

For governance to have effective jurisdiction over participants, there must be some degree of agreement by all participants that they will abide by the governance mandates. A minimal degree of agreement often presages participants who "slow-roll" if not actively rejecting compliance with Policies that express the specifics of governance.

2529 5.1.2.2 Setting Up Governance

2530

2531 Figure 35 - Setting Up Governance

2532 Leadership

Leadership is the entity who has the responsibility and authority to generate consistent policies
 through which the goals of governance can be expressed and to define and champion the
 structures and processes through which governance is realized.

2536 Governance Framework

2537The Governance Framework is a set of organizational structures that enable governance to be2538consistently defined, clarified, and as needed, modified to respond to changes in its domain of2539concern.

2540 Governance Processes

2541Governance Processes are the defined set of activities that are performed within the Governance2542Framework to enable the consistent definition, application, and as needed, modification of Rules2543that organize and regulate the activities of participants for the fulfillment of expressed policies.2544(See section 5.1.2.3 for elaboration on the relationship of Governance Processes and Rules.)

As noted earlier, governance requires an appropriate organizational structure and identification of who has authority to make governance decisions. In Figure 35, the entity with governance authority is designated the Leadership. This is someone, possibly one or more of the participants, which participants recognize as having authority for a given purpose or over a given set of issues or concerns.

The Leadership is responsible for prescribing or delegating a working group to prescribe the Governance Framework that forms the structure for Governance Processes which define how governance is to be carried out. This does not itself define the specifics of how governance is to be applied, but it does provide an unambiguous set of procedures that should ensure consistent actions which participants agree are fair and account for sufficient input on the subjects to which governance is applied.

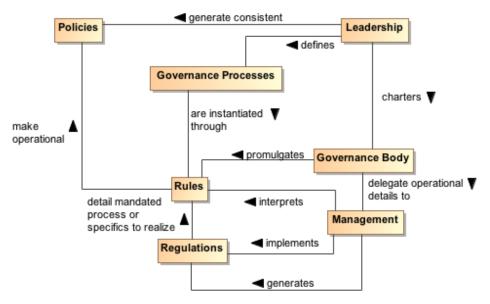

The participants may be part of the working group that codifies the Governance Framework and Processes. When complete, the participants must acknowledge and agree to abide by the products generated through application of this structure.

The Governance Framework and Processes are often documented in the charter of a body created or designated to oversee governance. This is discussed further in the next section. Note that the

2559 Governance Processes should also include those necessary to modify the Governance Framework itself.

An important function of Leadership is not only to initiate but also be the consistent champion of governance. Those responsible for carrying out governance mandates must have Leadership who make it clear to participants that expressed Policies are seen as a means to realizing established goals and that compliance with governance is required.

2564 5.1.2.3 Carrying Out Governance

2565

2569

2566 Figure 36 - Carrying Out Governance

2567 Rule

2568

A Rule is a prescribed guide for carrying out activities and processes leading to desired results, e.g. the operational realization of policies.

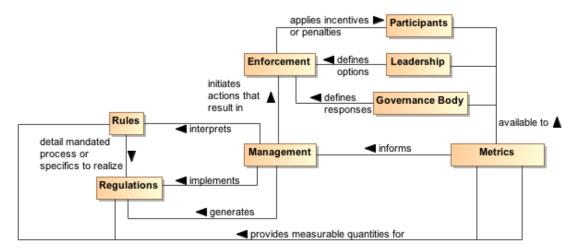

2570 Regulation

2571A Regulation is a mandated process or the specific details that derive from the interpretation of2572Rules and lead to measureable quantities against which compliance can be measured.

2573 To carry out governance, Leadership charters a Governance Body to promulgate the Rules needed to 2574 make the Policies operational. The Governance Body acts in line with Governance Processes for its rulemaking process and other functions. Whereas Governance is the setting of Policies and defining the 2575 Rules that provide an operational context for Policies, the operational details of governance may be 2576 delegated by the Governance Body to Management. Management generates Regulations that specify 2577 2578 details for Rules and other procedures to implement both Rules and Regulations. For example, Leadership could set a Policy that all authorized parties should have access to data, the Governance 2579 Body would promulgate a Rule that PKI certificates are required to establish identity of authorized parties, 2580 2581 and Management can specify a Regulation of who it deems to be a recognized PKI issuing body. In 2582 summary, Policy is a predicate to be satisfied and Rules prescribe the activities by which that satisfying 2583 occurs. A number of rules may be required to satisfy a given policy; the carrying out of a rule may contribute to several policies being realized. 2584

2585 Whereas the Governance Framework and Processes are fundamental for having participants 2586 acknowledge and commit to compliance with governance, the Rules and Regulations provide operational 2587 constraints which may require resource commitments or other levies on the participants. It is important 2588 for participants to consider the framework and processes to be fair, unambiguous, and capable of being 2589 carried out in a consistent manner and to have an opportunity to formally accept or ratify this situation. Rules and Regulations, however, do not require individual acceptance by any given participant although 2590 2591 some level of community comment may be part of the Governance Processes. Having agreed to 2592 governance, the participants are bound to comply or be subject to prescribed mechanisms for 2593 enforcement.

2594 5.1.2.4 Ensuring Governance Compliance

2595

2596 Figure 37 - Ensuring Governance Compliance

Setting Rules and Regulations does not ensure effective governance unless compliance can be measured and Rules and Regulations can be enforced. Metrics are those conditions and quantities that can be measured to characterize actions and results. Rules and Regulations MUST be based on collected Metrics or there is no means for Management to assess compliance. The Metrics are available to the participants, the Leadership, and the Governance Body so what is measured and the results of measurement are clear to everyone.

The Leadership in its relationship with participants has certain options that can be used for Enforcement.
 A common option may be to affect future funding. The Governance Body defines specific enforcement
 responses, such as what degree of compliance is necessary for full funding to be restored. It is up to
 Management to identify compliance shortfalls and to initiate the Enforcement process.

Note, enforcement does not strictly need to be negative consequences. Management can use Metrics to
 identify exemplars of compliance and Leadership can provide options for rewarding the participants. The
 Governance Body defines awards or other incentives.

2610 **5.1.2.5 Considerations for Multiple Governance Chains**

As noted in section 5.1.2, instances of the governance model often occur as a tiered arrangement, with governance at some level delegating specific authority and responsibility to accomplish a focused portion of the original level's mandate. For example, a corporation may encompass several lines of business and each line of business governs its own affairs in a manner that is consistent with and contributes to the goals of the parent organization. Within the line of business, an IT group may be given the mandate to provide and maintain IT resources, giving rise to IT governance.

In addition to tiered governance, there may be multiple governance chains working in parallel. For
example, a company making widgets has policies intended to ensure they make high quality widgets and
make an impressive profit for their shareholders. On the other hand, Sarbanes-Oxley is a parallel
governance chain in the United States that specifies how the management must handle its accounting
and information that needs to be given to its shareholders. The parallel chains may just be additive or
may be in conflict and require some harmonization.

Being distributed and representing different ownership domains, a SOA participant falls under the jurisdiction of multiple governance domains simultaneously and may individually need to resolve consequent conflicts. The governance domains may specify precedence for governance conformance or it may fall to the discretion of the participant to decide on the course of actions they believe appropriate.

2627 **5.1.3 Governance Applied to SOA**

2628 5.1.3.1 Where SOA Governance is Different

2629 SOA governance is often discussed in terms of IT governance, but rather than a parent-child relationship, 2630 Figure 38 shows the two as siblings of the general governance described in section 5.1.2. There are 2631 obvious dependencies and a need for coordination between the two, but the idea of aligning IT with business already demonstrates that resource providers and resource consumers must be working 2632 towards common goals if they are to be productive and efficient. While SOA governance is shown to be 2633 active in the area of infrastructure, it is a specialized concern for having a dependable platform to support 2634 2635 service interaction; a range of traditional IT issues is therefore out of scope of this document. A SOA governance plan for an enterprise will not of itself resolve shortcomings with the enterprise's IT 2636 2637 governance.

2638 Governance in the context of SOA is that organization of services: that promotes their visibility; that 2639 facilitates interaction among service participants; and that directs that the results of service interactions 2640 are those real world effects as described within the service description and constrained by policies and 2641 contracts as assembled in the execution context.

SOA governance must specifically account for control across different ownership domains, i.e. all the participants may not be under the jurisdiction of a single governance authority. However, for governance to be effective, the participants must agree to recognize the authority of the Governance Body and must operate within the Governance Framework and through the Governance Processes so defined.

SOA governance must account for interactions across ownership boundaries, which may also imply across enterprise governance boundaries. For such situations, governance emphasizes the need for agreement that some Governance Framework and Governance Processes have jurisdiction, and the governance defined must satisfy the Goals of the participants for cooperation to continue. A standards development organization such as OASIS is an example of voluntary agreement to governance over a limited domain to satisfy common goals.

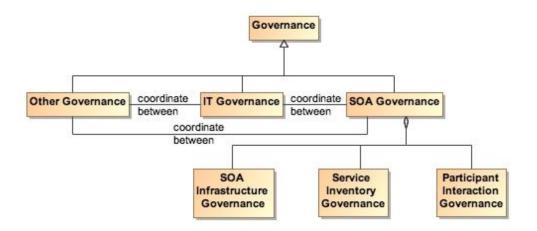

The specifics discussed in the figures in the previous sections are equally applicable to governance across ownership boundaries as it is within a single boundary. There is a charter agreed to when participants become members of the organization, and this charter sets up the structures and processes to be followed. Leadership may be shared by the leadership of the overall organization and the leadership of individual groups themselves chartered per the Governance Processes. There are Rules/Regulations specific to individual efforts for which participants agree to local goals, and Enforcement can be loss of voting rights or under extreme circumstances, expulsion from the group.

2659 Thus, the major difference for SOA governance is an appreciation for the cooperative nature of the 2660 enterprise and its reliance on furthering common goals if productive participation is to continue.

2661 5.1.3.2 What Must be Governed

An expected benefit of employing SOA principles is the ability to quickly bring resources to bear to deal with unexpected and evolving situations. This requires a great deal of confidence in the underlying capabilities that can be accessed and in the services that enable the access. It also requires considerable flexibility in the ways these resources can be employed. Thus, SOA governance requires establishing confidence and trust while instituting a solid framework that enables flexibility, indicating a combination of strict control over a limited set of foundational aspects but minimum constraints beyond those bounds.

2669

2670

2671 Figure 38 - Relationship Among Types of Governance

- 2672 SOA governance applies to three aspects of service definition and use:
- SOA infrastructure the "plumbing" that provides utility functions that enable and support the use of the service
- Service inventory the requirements on a service to permit it to be accessed within the infrastructure
- Participant interaction the consistent expectations with which all participants are expected to comply

2679 5.1.3.2.1 Governance of SOA Infrastructure

The SOA infrastructure is likely composed of several families of SOA services that provide access to fundamental computing business services. These include, among many others, services such as messaging, security, storage, discovery, and mediation. The provisioning of an infrastructure on which these services may be accessed and the general realm of those contributing as utility functions of the infrastructure are a traditional IT governance concern. In contrast, the focus of SOA governance is how the existence and use of the services enables the SOA ecosystem.

2686 By characterizing the environment as containing families of SOA services, the assumption is that there may be multiple approaches to providing the business services or variations in the actual business 2687 services provided. For example, discovery could be based on text search, on metadata search, on 2688 approximate matches when exact matches are not available, and numerous other variations. The 2689 2690 underlying implementation of search algorithms are not the purview of SOA governance, but the access 2691 to the resulting service infrastructure enabling discovery must be stable, reliable, and extremely robust to 2692 all operating conditions. Such access enables other specialized SOA services to use the infrastructure in 2693 dependable and predictable ways, and is where governance is important.

2694 5.1.3.2.2 Governance of the Service Inventory

Given an infrastructure in which other SOA services can operate, a key governance issue is which SOA
services to allow in the ecosystem. The major concern SHOULD be a definition of well-behaved services,
where the required behavior will inherit their characteristics from experiences with distributed computing
but also evolve with SOA experience. A major requirement for ensuring well-behaved services is
collecting sufficient metrics to know how the service affects the SOA infrastructure and whether it
complies with established infrastructure policies.

Another common concern of service approval is whether there is a possibility of duplication of function by multiple services. Some governance models talk to a tightly controlled environment where a primary concern is to avoid any service duplication. Other governance models talk to a market of services where the consumers have wide choices. For the latter, it is anticipated that the better services will emerge from market consensus and the availability of alternatives will drive innovation.

- Some combination of control and openness will emerge, possibly with a different appropriate balance for
- different categories of use. For SOA governance, the issue is less which services are approved but rather ensuring that sufficient description is available to support informed decisions for appropriate use. Thus,
- 2708 ensuring that sufficient description is available to support informed decisions for appropriate use. Thus,
- 2709 SOA governance SHOULD concentrate on identifying the required attributes to adequately describe a 2710 service, the required target values of the attributes, and the standards for defining the meaning of the
- 2710 service, the required target values of the attributes, and the standards for defining the meaning of the 2711 attributes and their target values. Governance may also specify the processes by which the attribute
- values are measured and the corresponding certification that some realized attribute set may imply.
- 2713 For example, unlimited access for using a service may require a degree of life cycle maturity that has
- 2714 demonstrated sufficient testing over a certain size community. Alternately, the policy may specify that a
- 2715 service in an earlier phase of its life cycle may be made available to a smaller, more technically
- sophisticated group in order to collect the metrics that would eventually allow the service to advance itslife cycle status.
- This aspect of governance is tightly connected to description because, given a well-behaved set of
 services, it is the responsibility of the consumer (or policies promulgated by the consumer's organization)
 to decide whether a service is sufficient for that consumer's intended use. The goal is to avoid global
 governance specifying criteria that are too restrictive or too lax for the local needs of which global
 governance has little insight.
- 2723 Such an approach to specifying governance allows independent domains to describe services in local 2724 terms while still having the services available for informed use across domains. In addition, changes to
- the attribute sets within a domain can be similarly described, thus supporting the use of newly described with the existing ones without having to update the description of all the legacy content.

2120 resources with the existing ones without having to update the description of all the legacy conte

2727 5.1.3.2.3 Governance of Participant Interaction

- Finally, given a reliable services infrastructure and a predictable set of services, the third aspect of governance is prescribing what is required during a service interaction.
- 2730 Governance would specify adherence to service interface and service reachability parameters and would 2731 require that the result of an interaction MUST correspond to the real world effects as contained in the
- 2732 service description. Governance would ensure preconditions for service use are satisfied, in particular 2733 those related to security aspects such as user authentication, authorization, and non-repudiation. If
- 2734 conflicts arise, governance would specify resolution processes to ensure appropriate agreements,
- 2735 policies, and conditions are met.
- 2736 It would also rely on sufficient monitoring by the SOA infrastructure to ensure services remain well-
- behaved during interactions, e.g. do not use excessive resources or exhibit other prohibited behavior.
- 2738 Governance would also require that policy agreements as documented in the execution context for the 2739 interaction are observed and that the results and any after effects are consistent with the agreed policies.
- 2739 Governance focuses on more contractual and legal aspects rather than the precursor descriptive aspects.
- 2740 Sovemance rocuses on more contractual and legal aspects rather than the precursor descriptive aspects. 2741 SOA governance may prescribe the processes by which SOA-specific policies are allowed to change, but
- there are probably more business-specific policies that will be governed by processes outside SOA
 governance.

2744 **5.1.3.3 Overarching Governance Concerns**

- There are numerous governance related concerns whose effects span the three areas just discussed. One is the area of standards, how these are mandated, and how the mandates may change. The Web Services standards stack is an example of relevant standards where a significant number are still under development. In addition, while there are notional scenarios that guide what standards are being developed, the fact that many of these standards do not yet exist precludes operational testing of their adequacy or effectiveness as a necessary and sufficient set.
- That said, standards are critical to creating a SOA ecosystem where SOA services can be introduced, used singularly, and combined with other services to deliver complex business functionality. As with other aspects of SOA governance, the Governance Body should identify the minimum set felt to be needed and rigorously enforce that that set be used where appropriate. The Governance Body takes care to expand and evolve the mandated standards in a predictable manner and with sufficient technical quidance that new services are able to coexist as much as possible with the old, and changes to
- 2757 standards do not cause major disruptions.

Another area that may see increasing activity as SOA expands is additional regulation by governments and associated legal institutions. New laws may deal with transactions which are service based, possibly including taxes on the transactions. Disclosure laws may mandate certain elements of description so both the consumer and provider act in a predictable environment and are protected from ambiguity in intent or action. Such laws spawn rules and regulations that will influence the metrics collected for evaluation of compliance.

2764 5.1.3.4 Considerations for SOA Governance

2800

2801

2802 2803

2804

2805

2806

2807

The Reference Architecture definition of a loosely coupled system is one in which the constraints on the interactions between components is minimal: sufficient to permit interoperation without additional constraints that may be an artifact of implementation technology. While governance experience for standalone systems provides useful guides, we must be careful not to apply constraints that would preclude the flexibility, agility, and adaptability we expect to realize from a SOA ecosystem.

2770 One of the strengths of SOA is it can make effective use of diversity rather than requiring monolithic 2771 solutions. Heterogeneous organizations can interact without requiring each conforms to uniform tools, 2772 representation, and processes. However, with this diversity comes the need to adequately define those elements necessary for consistent interaction among systems and participants, such as which 2773 communication protocol, what level of security, which vocabulary for payload content of messages. The 2774 2775 solution is not always to lock down these choices but to standardize alternatives and standardize the representations through which an unambiguous identification of the alternative chosen can be conveyed. 2776 For example, the URI standard specifies the URI string, including what protocol is being used, what is the 2777 2778 target of the message, and how parameters may be attached. It does not limit the available protocols, the 2779 semantics of the target address, or the parameters that can be transferred. Thus, as with our definition of loose coupling, it provides absolute constraints but minimizes which constraints it imposes. 2780

There is not a one-size-fits-all governance but a need to understand the types of things governance is called upon to do in the context of the goals of SOA. Some communities may initially desire and require very stringent governance policies and procedures while others see need for very little. Over time, best practices will evolve, resulting in some consensus on a sensible minimum and, except in extreme cases where it is demonstrated to be necessary, a loosening of strict governance toward the best practice mean.

2787 A question of how much governance may center on how much time governance activities require versus how quickly is the system being governed expected to respond to changing conditions. For large single 2788 2789 systems that take years to develop, the governance process could move slowly without having a serious 2790 negative impact. For example, if something takes two years to develop and the steps involved in governance take two months to navigate, then the governance can go along in parallel and may not have 2791 a significant impact on system response to changes. Situations where it takes as long to navigate 2792 governance requirements as it does to develop a response are examples where governance may need to 2793 2794 be reevaluated as to whether it facilitates or inhibits the desired results. Thus, the speed at which 2795 services are expected to appear and evolve needs to be considered when deciding the processes for 2796 control. The added weight of governance should be appropriate for overall goals of the application 2797 domain and the service environment.

- 2798 Governance, as with other aspects of any SOA implementation, should start small and be conceptualized 2799 in a way that keeps it flexible, scalable, and realistic. A set of useful guidelines would include:
 - Do not hardwire things that will inevitably change. For example, develop a system that uses the representation of policies rather than code the policies into the implementations.
 - Avoid setting up processes that demo well for three services without considering how they may
 work for 300. Similarly, consider whether the display of status and activity for a small number of
 services will also be effective for an operator in a crisis situation looking at dozens of services,
 each with numerous, sometimes overlapping and sometimes differing activities.
 - Maintain consistency and realism. A service solution responding to a natural disaster cannot be expected to complete a 6-week review cycle but be effective in a matter of hours.

2808 **5.1.4 Architectural Implications of SOA Governance**

- 2809 The description of SOA governance indicates numerous architectural requirements on the SOA2810 ecosystem:
- Governance is expressed through policies and assumes multiple use of focused policy modules 2811 • that can be employed across many common circumstances. This requires the existence of: 2812 descriptions to enable the policy modules to be visible, where the description includes a 2813 0 2814 unique identifier for the policy and a sufficient, and preferably a machine process-able, 2815 representation of the meaning of terms used to describe the policy, its functions, and its 2816 effects: one or more discovery mechanisms that enable searching for policies that best meet the 2817 0 2818 search criteria specified by the service participant; where the discovery mechanism will have access to the individual policy descriptions, possibly through some repository 2819 2820 mechanism: 2821 accessible storage of policies and policy descriptions, so service participants can access, 0 2822 examine, and use the policies as defined. Governance requires that the participants understand the intent of governance, the structures 2823 created to define and implement governance, and the processes to be followed to make 2824 2825 governance operational. This requires the existence of: 2826 an information collection site, such as a Web page or portal, where governance 0 2827 information is stored and from which the information is always available for access; a mechanism to inform participants of significant governance events, such as changes in 2828 0 2829 policies, rules, or regulations; 2830 accessible storage of the specifics of Governance Processes; 0 2831 SOA services to access automated implementations of the Governance Processes \circ 2832 Governance policies are made operational through rules and regulations. This requires the 2833 existence of: 2834 descriptions to enable the rules and regulations to be visible, where the description 0 includes a unique identifier and a sufficient, and preferably a machine process-able. 2835 representation of the meaning of terms used to describe the rules and regulations; 2836 one or more discovery mechanisms that enable searching for rules and regulations that 2837 \circ 2838 may apply to situations corresponding to the search criteria specified by the service 2839 participant; where the discovery mechanism will have access to the individual 2840 descriptions of rules and regulations, possibly through some repository mechanism; 2841 accessible storage of rules and regulations and their respective descriptions, so service 0 2842 participants can understand and prepare for compliance, as defined. SOA services to access automated implementations of the Governance Processes. 2843 Governance implies management to define and enforce rules and regulations. Management is 2844 discussed more specifically in section 5.3, but in a parallel to governance, management requires 2845 2846 the existence of: 2847 an information collection site, such as a Web page or portal, where management 0 2848 information is stored and from which the information is always available for access; 2849 0 a mechanism to inform participants of significant management events, such as changes 2850 in rules or regulations; 2851 accessible storage of the specifics of processes followed by management. 2852 Governance relies on metrics to define and measure compliance. This requires the existence of: the infrastructure monitoring and reporting information on SOA resources: 2853 0 2854 possible interface requirements to make accessible metrics information generated or 0 most easily accessed by the service itself. 2855

2856 **5.2 Security Model**

2857 Security is one aspect of confidence – the confidence in the integrity, reliability, and confidentiality of the 2858 system. In particular, security focuses on those aspects of assurance that involve the accidental or malign 2859 intent of other people to damage or compromise trust in the system and on the availability of SOA-based 2860 systems to perform desired capability.

2861 Security

2862 Security concerns the set of mechanisms for ensuring and enhancing trust and confidence in the 2863 SOA ecosystem.

Providing for security for Service Oriented Architecture is somewhat different than for other contexts; although many of the same principles apply equally to SOA and to other systems. The fact that SOA embraces crossing ownership boundaries makes the issues involved with moving data more visible.

As well as securing the movement of data within and across <u>ownership boundaries</u>, security often revolves around <u>resources</u>: the need to guard certain resources against inappropriate access – whether reading, writing or otherwise manipulating those resources.

- Any comprehensive security solution must take into account the people that are using, maintaining and managing the SOA. Furthermore, the relationships between them must also be incorporated: any security assertions that may be associated with particular interactions originate in the people that are behind the interaction.
- We analyze security in terms of the social structures that define the legitimate permissions, obligations and roles of people in relation to the system, and mechanisms that must be put into place to realize a secure system. The former are typically captured in a series of security policy statements; the latter in
- 2877 terms of security *guards* that ensure that policies are enforced.
- 2878 How and when to apply these derived security policy mechanisms is directly associated with the
- 2879 assessment of the *threat model* and a *security response model*. The threat model identifies the kinds of 2880 threats that directly impact the message and/or application of constraints, and the response model is the
- proposed mitigation to those threats. Properly implemented, the result can be an acceptable level of risk
- to the safety and integrity of the system.

2883 **5.2.1 Secure Interaction Concepts**

- 2884 We can characterize secure interactions in terms of key security concepts **[ISO/IEC 27002]**:
- confidentiality, integrity, authentication, authorization, non-repudiation, and availability. The concepts for
 secure interactions are well defined in other standards and publications. The security concepts here are
 not defined but rather related to the SOA ecosystem perspective of the SOA-RAF.

2888 5.2.1.1 Confidentiality

- 2889 Confidentiality concerns the protection of privacy of participants in their interactions. Confidentiality refers 2890 to the assurance that unauthorized entities are not able to read messages or parts of messages that are 2891 transmitted.
- Note that confidentiality has degrees: in a completely confidential exchange, third parties would not even be aware that a confidential exchange has occurred. In a partially confidential exchange, the identities of
- the participants may be known but the content of the exchange obscured.

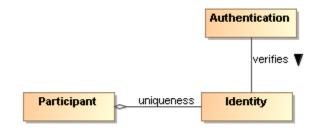

2895 5.2.1.2 Integrity

- Integrity concerns the protection of information that is exchanged either from unauthorized writing or
 inadvertent corruption. Integrity refers to the assurance that information that has been exchanged has not
 been altered.
- Integrity is different from confidentiality in that messages that are sent from one participant to another
 may be obscured to a third party, but the third party may still be able to introduce his own content into the
 exchange without the knowledge of the participants.
- 2902 Section 5.2.4 describes common computing techniques for providing confidentiality and integrity during 2903 message exchanges.

2904 5.2.1.3 Authentication

Authentication concerns the identity of the participants in an exchange. Authentication refers to the means by which one participant can be assured of the identity of other participants. 2907

- 2908 Figure 39 Authentication
- 2909 applies authentication to the identity of participants.

2910

2911 Figure 39 - Authentication

2912 5.2.1.4 Authentication

- Authorization concerns the legitimacy of the interaction. Authorization refers to the means by which a
- stakeholder may be assured that the information and actions that are exchanged are either explicitly or implicitly approved.
 - Authority empowered with 🛦 Stakeholder defines 🔻 Policy rules for V <<assess>> Authorization Role <<require>> <<assess>> Authentication Reputation <<assess>> Attributes <<require>> <<require>> <<require>> participates Joint Action participates Speaking Action Listening Action

2916

2917 Figure 40 - Authorization

The roles and attributes which provide a participant's credentials are expanded to include reputation. Reputation often helps determine willingness to interact, for example, reviews of a service provider will influence the decision to interact with the service provider. The roles, reputation, and attributes are represented as assertions measured by authorization decision points. The role of policy for security is to permit stakeholders to express their choices. In Figure 40, a policy is a written constraint and the role, reputation, and attribute assertions are evaluated according to the constraints in the authorization policy. A combination of security mechanisms and their control via explicit policies can form the basis of an authorization solution.

2926 5.2.1.5 Non-repudiation

Non-repudiation concerns the accountability of participants. To foster trust in the performance of a system used to conduct shared activities it is important that the participants are not able to later deny their actions: to repudiate them. Non-repudiation refers to the means by which a participant may not, at a later time, successfully deny having participated in the interaction or having performed the actions as reported by other participants.

2932 **5.2.1.6 Availability**

Availability concerns the ability of systems to use and offer the services for which they were designed.
One of the threats against availability is the so-called denial of service attack in which attackers attempt to
prevent legitimate access to the system.

2936 We differentiate here between general availability – which includes aspects such as systems reliability – 2937 and availability as a security concept where we need to respond to active threats to the system.

2938 5.2.2 Where SOA Security is Different

2939 The core security concepts are fundamental to all social interactions. The evolution of sharing

- information using a SOA requires the flexibility to dynamically secure computing interactions in a
 computing ecosystem where the owning social groups, roles, and authority are constantly changing as
 described in section 5.1.3.1.
- 2943 SOA policy-based security can be more adaptive for a computing ecosystem than previous computing 2944 technologies allow for, and typically involves a greater degree of distributed mechanisms.
- Standards for security, as is the case with all aspects of SOA, play a large role in flexible security on a
 global scale. SOA security may also involve greater auditing and reporting to adhere to regulatory
 compliance established by governance structures.

2948 5.2.3 Security Threats

There are a number of ways in which an attacker may attempt to compromise the security of a system. The two primary sources of attack are third parties attempting to subvert interactions between legitimate participants and an entity that is participating but attempting to subvert its partner(s). The latter is particularly important in a SOA where there may be multiple ownership boundaries and trust boundaries.

The threat model lists some common threats that relate to the core security concepts listed in Section 5.2.1. Each technology choice in the realization of a SOA can potentially have many threats to consider.

2955 Message alteration

- 2956If an attacker is able to modify the content (or even the order) of messages that are exchanged2957without the legitimate participants being aware of it then the attacker has successfully2958compromised the security of the system. In effect, the participants may unwittingly serve the2959needs of the attacker rather than their own.
- 2960 An attacker may not need to completely replace a message with his own to achieve his objective: 2961 replacing the identity of the beneficiary of a transaction may be enough.

2962 Message interception

If an attacker is able to intercept and understand messages exchanged between participants,
then the attacker may be able to gain advantage. This is probably the most commonly understood
security threat.

2966 Man in the middle

- In a man-in-the-middle attack, the legitimate participants believe that they are interacting with
 each other; but are in fact interacting with the attacker. The attacker attempts to convince each
 participant that he is their correspondent; whereas in fact he is not.
- In a successful man-in-the-middle attack, legitimate participants do not have anaccurate
 understanding of the state of the other participants. The attacker can use this to subvert the
 intentions of the participants.

2973 Spoofing

In a spoofing attack, the attacker convinces a participant that he is really someone else –
 someone that the participant would normally trust.

2976 Denial of service attack

- 2977In a denial of service (DoS) attack, the attacker attempts to prevent legitimate users from making2978use of the service. A DoS attack is easy to mount and can cause considerable harm: by2979preventing legitimate interactions, or by slowing them down enough, the attacker may be able to2980simultaneously prevent legitimate access to a service and to attack the service by another2981means.
- 2982A variation of the DoS attack is the Distributed Denial of Service attack. In a DDoS attack the
attacker uses multiple agents to the attack the target. In some circumstances this can be
extremely difficult to counteract effectively.
- 2985 One of the features of a DoS attack is that it does not require valid interactions to be effective: 2986 responding to invalid messages also takes resources and that may be sufficient to cripple the 2987 target.

2988 Replay attack

- 2989In a replay attack, the attacker captures the message traffic during a legitimate interaction and2990then replays part of it to the target. The target is persuaded that a similar transaction to the2991previous one is being repeated and it responds as though it were a legitimate interaction.
- A replay attack may not require that the attacker understand any of the individual communications; the attacker may have different objectives (for example attempting to predict how the target would react to a particular request).

2995 False repudiation

2996In false repudiation, a user completes a normal transaction and then later attempts to deny that2997the transaction occurred. For example, a customer may use a service to buy a book using a credit2998card; then, when the book is delivered, refuse to pay the credit card bill claiming that someone2999else must have ordered the book.

3000 **5.2.4 Security Responses**

Security goals are never absolute: it is not possible to guarantee 100% confidentiality, non-repudiation,
 etc. However, a well designed and implemented security response model can ensure acceptable levels of
 security risk. For example, using a well-designed cipher to encrypt messages may make the cost of
 breaking communications so great and so lengthy that the information obtained is valueless.

Performing threat assessments, devising mitigation strategies, and determining acceptable levels of risk are the foundation for an effective process to mitigating threats in a cost-effective way.¹¹ The choice in hardware and software to realize a SOA will be a basis for threat assessments and mitigation strategies. The stakeholders of a specific SOA implementation should determine acceptable levels of risk based on threat assessments and the cost of mitigating those threats.

3010 **5.2.4.1 Privacy Enforcement**

- 3011 The most efficient mechanism to assure confidentiality is the encryption of information. Encryption is
- 3012 particularly important when messages must cross trust boundaries; especially over the Internet. Note that 3013 encryption need not be limited to the content of messages: it is possible to obscure even the existence of 3014 messages themselves through encryption and 'white noise' generation in the communications channel.
- 3015 The specifics of encryption are beyond the scope of this architecture. However, we are concerned about 3016 how the connection between privacy-related policies and their enforcement is made.
- A policy enforcement point for enforcing privacy may take the form of an automatic function to encrypt
 messages as they leave a trust boundary; or perhaps simply ensuring that such messages are suitably
 encrypted.
- Any policies relating to the level of encryption being used would then apply to these centralized messaging functions.

3022 5.2.4.2 Integrity Protection

- To protect against message tampering or inadvertent message alteration, and to allow the receiver of a message to authenticate the sender, messages may be accompanied by a digital signature. Digital signatures provide a means to detect if signed data has been altered. This protection can also extend to authentication and non-repudiation of a sender.
- A common way a digital signature is generated is with the use of a private key that is associated with a public key and a digital certificate. The private key of some entity in the system is used to create a digital signature for some set of data. Other entities in the system can check the integrity of the signed data set via signature verification algorithms. Any changes to the data that was signed will cause signature verification to fail, which indicates that integrity of the data set has been compromised.
- A party verifying a digital signature must have access to the public key that corresponds to the private key used to generate the signature. A digital certificate contains the public key of the owner, and is itself protected by a digital signature created using the private key of the issuing Certificate Authority (CA).

3035 **5.2.4.3 Message Replay Protection**

- To protect against replay attacks, messages may contain information that can be used to detect replayed messages. The simplest requirement to prevent replay attacks is that each message that is ever sent is unique. For example, a message may contain a message ID, a timestamp, and the intended destination.
- 3039 By storing message IDs, and comparing each new message with the store, it becomes possible to verify 3040 whether a given message has been received before (and therefore should be discarded).

¹¹ In practice, there are perceptions of security from all participants regardless of ownership boundaries. Satisfying security policy often requires asserting sensitive information about the message initiator. The perceptions of this participant about information privacy may be more important than actual security enforcement within the SOA for this stakeholder.

- 3041 The timestamp may be included in the message to help check for message freshness. Messages that
- 3042 arrive after their message ID could have been cleared (after receiving the same message some time 3043 previously) may also have been replayed. A common means for representing timestamps is a useful part 3044 of an interoperable replay detection mechanism.
- 3045 The destination information is used to determine if the message was misdirected or replayed. If the 3046 replayed message is sent to a different endpoint than the destination of the original message, the replay 3047 could go undetected if the message does not contain information about the intended destination.
- 3048 In the case of messages that are replies to prior messages, it is also possible to include seed information in the prior messages that is randomly and uniquely generated for each message that is sent out. A 3049 replay attack can then be detected if the reply does not embed the random number that corresponds to 3050 3051 the original message.

3052 5.2.4.4 Auditing and Logging

- 3053 False repudiation involves a participant denying that it authorized a previous interaction. An effective 3054 strategy for responding to such a denial is to maintain careful and complete logs of interactions which can 3055 be used for auditing purposes. The more detailed and comprehensive an audit trail is, the less likely it is 3056 that a false repudiation would be successful.
- 3057 The countermeasures assume that the non-repudiation tactic (e.g. digital signatures) is not undermined 3058 itself. For example, if private key is stolen and used by an adversary, even extensive logging cannot 3059 assist in rejecting a false repudiation.
- 3060 Unlike many of the security responses discussed here, it is likely that the scope for automation in rejecting a repudiation attempt is limited to careful logging. 3061

3090

3063 The key to managing and responding to DoS attacks is to be careful in the use of resources when 3064 responding to interaction. Put simply, a system has a choice to respond to a communication or to ignore 3065 it. In order to avoid vulnerability to DoS attacks a service provider should be careful not to commit resources beyond those implied by the current state of interactions; this permits a graduation in 3066 3067 commitment by the service provider that mirrors any commitment on the part of service consumers and 3068 attackers alike.

5.2.5 Architectural Implications of SOA Security 3069

- 3070 Providing SOA security in an ecosystem of governed services has the following implications on the policy support and the distributed nature of mechanisms used to assure SOA security: 3071
 - Security expressed through policies have the same architectural implications as described in Section 4.4.3 for policies and contracts architectural implications.
- Security policies require mechanisms to support security description administration, storage, and 3074 • distribution. 3075
 - Service descriptions supporting security policies should:
 - have a meta-structure sufficiently rich to support security policies; \circ
 - be able to reference one or more security policy artifacts; 0
 - have a framework for resolving conflicts between security policies. 0
 - The mechanisms that make-up the execution context in secure SOA-based systems should:
 - provide protection of the confidentiality and integrity of message exchanges; 0
 - be distributed so as to provide centralized or decentralized policy-based identification. 0 authentication, and authorization;
 - ensure service availability to consumers: 0
 - be able to scale to support security for a growing ecosystem of services; 0
 - be able to support security between different communication technologies; 0
- 3087 Common security services include: 3088
 - services that abstract encryption techniques; 0
 - services for auditing and logging interactions and security violations; 0
 - services for identification; 0

- 3091 services for authentication; 3092
 - 0 services for authorization;
 - services for intrusion detection and prevention: 0
 - services for availability including support for quality of service specifications and metrics. 0

5.3 Management Model 3095

5.3.1 Management 3096

3093

3094

3102

3103

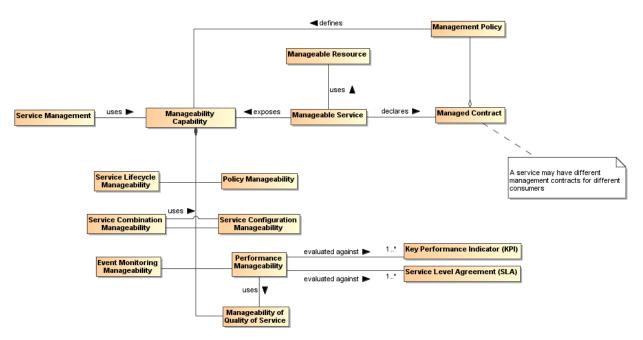

3110

3111

3112

- 3097 Management is a process of controlling resources in accordance with the policies and principles defined by Governance. 3098
- 3099 There are three separate but linked domains of interest within the management of SOA ecosystem:
- 3100 1. the management and support of the resources that are involved in any complex structures - of which SOA ecosystems are excellent examples; 3101
 - 2. the promulgation and enforcement of the policies and service contracts agreed to by the stakeholders in the SOA ecosystem;
- 3104 the management of the relationships of the participants – both to each other and to the services 3105 that they use and offer.
- 3106 There are many artifacts related to management. Historically, systems management capabilities have been organized by the "FCAPS" functions (based on ITU-T Rec. M.3400 (02/2000), "TMN Management 3107 3108 Functions"):
- 3109 fault management, •
 - configuration management,
 - account management,
 - performance and security management.
- 3113 The primary task of the functional groups is to concentrate on maintaining systems in a trusted, active, 3114 and accessible state.
- 3115 In the context of the SOA ecosystem, we see many possible resources that may require management 3116 such as services, service descriptions, service contracts, policies, roles, relationships, security, people 3117 and systems that implement services and infrastructure elements. In addition, given the ecosystem
- 3118 nature, it is also potentially necessary to manage the business relationships between participants.
- 3119 Successful operation of a SOA ecosystem requires trust among the stakeholders and between them and 3120 the SOA-based system elements. In contrast, regular systems in technology are not necessarily operated 3121 or used in an environment requiring trust before the stakeholders make use of the system. Indeed, many 3122 of these systems exist in hierarchical management structures, within which use may be mandated by legal requirement, executive decision, or good business practice in furthering the business' strategy. The 3123 pre-condition of trust in the SOA ecosystem is rooted both in the principles of service orientation and in 3124
- 3125 the distributed, authoritative ownership of independent services. Even for hierarchical management
- structures applied to a SOA ecosystem, the service in use should have a contractual basis rather than 3126 3127 being mandated.
- 3128 Trust may be established through agreements/contracts, policies, or implicitly through observation of
- 3129 repeated interactions with others. Explicit trust is usually accompanied by formalized documents suitable
- for management. Implicit trust adds fragility to the management of a SOA ecosystem because failure to 3130 3131 maintain consistent and predictable interactions will undermine the trust between participants and within
- 3132 the ecosystem as a whole.
- 3133 Management in a SOA ecosystem is thus concerned with management taking actions that will establish 3134 the condition of trust that must be present before engaging in service interactions. These concerns should 3135 largely be handled within the governance of the ecosystem. The policies, agreements, and practices 3136 defined through governance provide the boundaries within which management operates and for which 3137 management must provide enforcement and feedback. However, governance alone cannot foresee all 3138 circumstances but must offer sufficient guidance where agreement between all stakeholders cannot be 3139 reached. Management in these cases must be flexible and adaptable to handle unanticipated conditions 3140 without unnecessarily breaking trust relationships.

- 3141 Service management is the process manual, automated, or a combination of proactively monitoring
- and controlling the behavior of a service or a set of services. Service management operates under
- 3143 constraints attributed to the business and social context. Specific policies may be used to govern cross-
- boundary relationships. Managing solutions based on such policies (and that may be used across
- 3145 ownership boundaries) raises issues that are not typically present when managing a service within a
- single ownership domain. Care is therefore required in managing a service when the owner of the
 service, the provider of the service, the host of the service and mediators to the service may all belong to
- 3148 different stakeholders.
- 3149 Cross-boundary service management takes place in, at least, the following situations:
- using combinations of services that belong to different ownership domains
- using of services that mediate between ownership domains
- sharing monitoring and reporting means and results.
- 3153 These situations are particularly important in ecosystems that are highly decentralized, in which the 3154 participants interact as peers as well as in the "master-servant" mode.
- 3155 The management model shown in Figure 41 conveys how the SOA applies to managing services.
- 3156 Services management operates via service metadata, such as service lifecycles and attributes associated
- 3157 with service use, which are typically collected in or accessed through the service description.
- 3158

3159

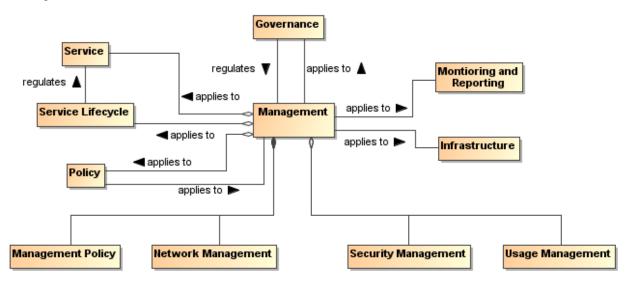

- 3160 Figure 41 Manageability capabilities in SOA ecosystem
- The service metadata of interest is that set of service properties that is manageable. These manageability properties are generally identifiable for any service consumed or supplied within the ecosystem. The necessary existence of these properties within the SOA ecosystem motivates the following definitions:
- 3164 **Manageability** of a resource is the capability that allows it to be controlled, monitored, and reported on 3165 with respect to some property. Note that manageability is not necessarily a part of the managed entities 3166 themselves and are generally considered to be external to the managed entities.
- Each resource may be managed through a number of aspects of management, and the resources maybe grouped based on similar aspects. For example, resources may be grouped according to the aspect
- referred to as "Configuration Manageability" for the collection of services. Some resources may not be
- managed under a particular capability if there are no manageability aspects with a clear meaning or use.
 As an example, all resources within a SOA ecosystem have a lifecycle that is meaningful within the
- 3172 ecosystem. Thus, all resources are manageable under Lifecycle Manageability. In contrast, not all

- 3173 resources report or handle events. Thus, Event Manageability is only concerned with those resources for3174 which events are meaningful.
- 3175 Life-cycle Manageability of a service typically refers to how the service is created, how it is destroyed
- and how service versions must be managed. This manageability is a feature of the SOA ecosystembecause the service cannot manage its own life cycle.
- 3178 Another important consideration is that services may have resource requirements that must be
- established at various points in the services' life cycles. However actual providers of these resources may
 not be known at the time of the service creation and, thus, have to be managed at service run-time.
- 3181 **Combination Manageability** of a service addresses management of service characteristics that allow for
- 3182 creating and changing combinations in which the service participates or that the service combines itself.
- 3183 Known models of such combinations are aggregations and compositions. Examples of patterns of 3184 combinations are choreography and orchestration. Combination Manageability drives implementation of
- 3184 combinations are choreography and orchestration. Combination Manageability drives implementation of 3185 the Service Composability Principle of service orientation.
- 3186 Service combination manageability resonates with the methodology of process management.
- 3187 Combination Manageability may be applied at different phases of service creation and execution and, in 3188 some cases, can utilize Configuration Manageability.
- 3189 Service combinations typically contribute the most in delivering business values to the stakeholders.
- 3190 Managing service combinations is the one of the most important tasks and features of the SOA 3191 ecosystem.
- 3192 **Configuration Manageability** of a service allows managing the identity of and the interactions among 3193 internal elements of the service. Also, Configuration Manageability correlates with the management of
- 3194 service versions and configuration of the deployment of new services into the ecosystem. Configuration
- 3195 Management differs from the Combination Manageability in the scope and scale of manageability, and
- 3196 addresses lower level concerns than the architectural combination of services.
- Event Monitoring Manageability allows managing the categories of events of interest related to services
 and reporting recognized events to the interested stakeholders. Such events may be the ones that trigger
 service invocations as well as execution of particular functionality provided by the service.
- Event Monitoring Manageability is a key lower-level manageability aspect that the service provider and associated stakeholders are interested. Monitored events may be internal or external to the SOA ecosystem. For example, a disaster in the oil industry, which is outside the SOA ecosystem of the Insurer, can trigger the service's functionality that is responsible for immediate or constant monitoring of oil prices in the oil trading exchanges and, respectively, modify the premium paid by the insured oil companies.
- Performance Manageability of a service allows controlling the service results, shared and sharable real
 world effects against the business goals and objectives of the service. This manageability assumes
 monitoring of the business performance as well as the management of this monitoring itself. Performance
 Manageability includes business and technical performance manageability through a performance criteria
 set, such as business key performance indicators (KPI) and service-level agreements (SLA).
- 3210 The performance business- and technical-level characteristics of the service should be known from the
- 3211 service contract. The service provider and consumer must be able to monitor and measure these
- 3212 characteristics or be informed about the results measured by a third party.
- Performance Manageability is the instrument for providing compliance of the service with its service
 contracts. Performance Manageability utilizes Manageability of Quality of Service.
- 3215 **Manageability of Quality of Service** deals with management of service non-functional characteristics 3216 that may be of significant value to the service consumers and other stakeholders in the SOA ecosystem.
- 3217 Classic examples of this include bandwidth offerings associated with a service.
- 3218 Manageability of quality of service assumes that the properties associated with service qualities are
- 3219 monitored during the service execution. Results of monitoring may be challenged against SLA and even 3220 KPI, which results in the continuous validation of how the service contract is preserved by the service
- 3221 provider.
- **Policy Manageability** allows additions, changes and replacements of the policies associated with a resource in the SOA ecosystem. The ability to manage those policies (such as promulgating policies,

- retiring policies and ensuring that policy decision points and enforcement points are current) enables the ecosystem to apply policies and *evaluate* the results.
- The capability to manage, i.e. use a particular manageability, requires policies from governance to be translated into detailed rules and regulations which are measured and monitored providing corresponding feedback for enforcement.
- 3229 Management of SOA ecosystem recognises the manageability challenge and requires manageability
- 3230 properties to be considered for all aforementioned manageability cases. In the following sub-sections, we
- describe how these properties are used in the management. Also we describe some relationships
- 3232 between management and other components of SOA ecosystem.

3233 **5.3.2 Management Means and Relationships**

A minimal set of management issues for the SOA ecosystem is shown on Figure 42 and elaborated in the following sections.

3236

3237 Figure 42 - Management Means and Relationships in SOA ecosystem

3238 5.3.2.1 Management Policy

The management of resources within the SOA ecosystem may be governed by management policies. In a deployed SOA-based solution, it may well be that different aspects of the management of a given service are managed by different management services. For example, the life-cycle management of services often involves managing service versions. Managing quality of service is often very specific to the service itself; for example, quality of service attributes for a video streaming service are quite different to those for a banking system.

3245 Additional concepts of management also apply to IT management.

3246 5.3.2.2 Network Management

- Network management deals with the maintenance and administration of large scale physical networks
 such as computer networks and telecommunication networks. Specifics of the networks may affect
 service interactions from performance and operational perspectives.
- 3250 Network and related system management executes a set of functions required for controlling, planning, 3251 deploying, coordinating, and monitoring the distributed services in the SOA ecosystem. However, while
- deploying, coordinating, and monitoring the distributed services in the SOA ecosystem. However, while recognizing their importance, the specifics of systems management or network management are out of
- 3253 scope for this Reference Architecture Foundation.

3254 5.3.2.3 Security Management

3255 Security Management includes identification of roles, permissions, access rights, and policy attributes 3256 defining security boundaries and events that may trigger a security response.

Security management within a SOA ecosystem is essential to maintaining the trust relationships between participants residing in different ownership domains. Security management must consider not just the internal properties related to interactions between participants but ecosystem properties that preserve the integrity of the ecosystem from external threats.

3261 **5.3.2.4 Usage Management**

3262 Usage Management is concerned with how resources are used, including:

- how the resource is accessed, who is using the resource, and the state of the resource (access properties);
- controlling or shaping demand for resources to optimize the overall operation of the ecosystem (demand properties);
 - with assigning costs to the use of resources and distributing those cost assignments to the participants in an appropriate manner (financial properties).

3269

3263 3264

3265

3266

3267

3268

3270 5.3.3 Management and Governance

The primary role of governance in the context of a SOA ecosystem is to foster an atmosphere of predictability, trust, and efficiency, and it accomplishes this by allowing the stakeholders to negotiate and set the key policies that govern the running of the SOA-based solution. Recall that in an ecosystems perspective, the goal of governance is less to have complete fine-grained control but more to enable the individual participants to work together.

- 3276 Policies for a SOA ecosystem will tend to focus on the rules of engagement between participants; for 3277 example, what kinds of interactions are permissible, how disputes are resolved, etc. While governance may primarily focus on setting policies, management will focus on the realization and enforcement of 3278 3279 policies. Effective management in the SOA ecosystem requires an ability for governance to understand 3280 the consequences of its policies, guidelines, and principles, and to adjust those as needed when 3281 inconsistencies or ambiguity become evident from the operation of the management functions. This 3282 understanding and adjustment must be facilitated by the results of management and so the mechanisms 3283 for providing feedback from management into governance must exist.
- 3283 for providing feedback from management into governance must exist.
 3284 Governance operates via specialized activities and, thus, should be managed itself. Governance policies
 3285 are included in the Governance Framework and Processor, and driven by the enterprise business medal
- are included in the Governance Framework and Processes, and driven by the enterprise business model,
 business objectives and strategies. Where corporate management policies exist, these are usually guided
 and directed by the corporate executives. In peer relationships, governance policies are set by either an
 external entity and accepted by the peers or by the peers themselves. This creates the appropriate
 authoritative level for the policies used for the management of the Governance Framework and
 Processes. Management to operationalize governance controls the life-cycle of the governing policies,
- 3291 including procedures and processes, for modifying the Governance Framework and Processes.

3292 **5.3.4 Management and Contracts**

3293 **5.3.4.1 Management for Contracts and Policies**

As we noted above, management can often be viewed as the application of contracts and individual policies to ensure the smooth running of the SOA ecosystem. Policies and service contracts specify the service characteristics that have to be monitored, analysed and managed and play an important role as the guiding constraints for management, as well as being artifacts (e.g., policy and contractual documents) that also need to be managed.

3299 **5.3.4.2 Contracts**

As described in sections "Participation in a SOA Ecosystem view" and "Realization of a SOA Ecosystem
 view", there are several types of contractual information in the SOA ecosystem. From the management
 perspective, three basic types of the contractual information relate to:

- relationship between service provider and consumer;
- communication with the service;
- control of the quality of the service execution.

When a consumer prepares to interact with a service, the consumer and the service provider must come to an agreement on the service features and characteristics that will be provided by the service and made available to the consumer. This agreement is known as a service contract.

3309 Service Contract

3314

3315

- 3310 An implicit or explicit documented agreement between the service consumer and service provider 3311 about the use of the service based on
- the commitment by a service provider to provide service functionality and results consistent with identified real world effects and
 - the commitment by a service consumer to interact with the service per specific means and per specified policies,
- 3316 where both consumer and provider actions are in the manner described in the service description.

3317 The service description provides the basis for the service contract and, in some situations, may be used 3318 as an implicit default service contract. In addition, the service description may set mandatory aspects of a service contract, e.g. for security services, or may specify acceptable alternatives. As an example of 3319 alternatives, the service description may identify which versions of a vocabulary will be recognized, and 3320 3321 the specifics of the contract are satisfied when the consumer uses one of the alternatives. Another 3322 alternative could have a consumer identify a policy they require be satisfied, e.g. a standard privacy policy 3323 on handling personal information, and a provider that is prepared to accept a policy request would 3324 indicate acceptance as part of the service contract by continuing with the interaction. In each of these 3325 cases, the actions of the participants are consistent with an implicit service contract without the existence 3326 of a formal agreement between the participants.

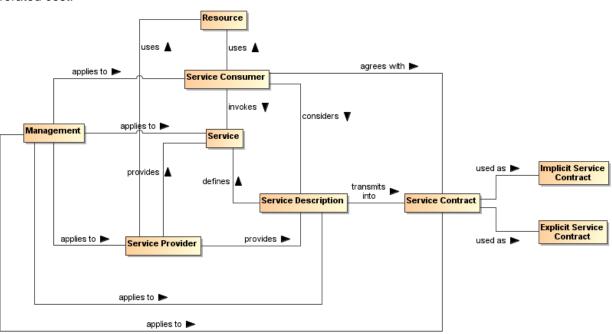

In the case of business services, it is anticipated that the service contract may take an explicit form and the agreement between business consumer and business service provider is formalized. Formalization

3329 requires up-front interactions between service consumer and service provider. In many business

3330 interactions, especially between business organizations within or across corporate boundaries, a

- 3331 consumer needs a contractual assurance from the provider or wants to explicitly indicate choices among
- alternatives, e.g., only use a subset of the business functionality offered by the service and pay a

3333 prorated cost.

3334

3335 Figure 43 - Management of the service interaction

3336 Consequently, an implicit service contract is an agreement (1) on the consumer side with the terms, 3337 conditions, features and interaction means specified in the service description "as is" or (2) a selection 3338 from alternatives that are made available through mechanisms included in the service description, and 3339 neither of these require any a priori interactions between the service consumer and the service provider. 3340 An explicit service contract always requires a form of interaction between the service consumer and the 3341 service provider prior to the service invocation. This interaction may regard the choice or selection of the 3342 subset of the elements of the service description or other alternatives introduced through the formal 3343 agreement process that would be applicable to the interaction with the service and affect related joint 3344 action.

3345 Any form of explicit contract couples the service consumer and provider. While explicit contracts may be 3346 necessary or desirable in some cases, such as in supply chain management, commerce often uses a mix 3347 of implicit and explicit contracts, and a service provider may offer (via service description) a conditional 3348 shift from implicit to explicit contract. For example, Twitter offers an implicit contract on the use of its APIs 3349 to any application with the limit on the amount of service invocations; if the application needs to use more 3350 invocations, one has to enter into the explicit fee-based contract with the provider. A case where an 3351 implicit contract transforms into an explicit contract may be illustrated when one buys a new computer and 3352 it does not work. The buyer returns the computer for repair under the manufacturer's warranty as stated by an implicit purchase contract. However, if the repair does not fix the problem and the seller offers an 3353 3354 upgraded model in replacement, the buyer may agree to an explicit contract that limits the rights of the 3355 buyer to make the explicit agreement public.

Control of the quality of the service execution, often represented as a service level agreement (SLA), is
performed by service monitoring systems and includes both technical and operational business controls.
SLA is a part of the service contract and, because of the individual nature of such contracts, may vary
from one service contract to another, even for the same consumer. Typically, a particular SLA in the
service contract is a concrete instance of the SLA declared in the service description.

Management of the service contracts is based on management policies that may be mentioned in the service description and in the service contracts. Management of the service contracts is mandatory for consumer relationship management. In the case of explicit service contracts, the contracts have to be created, stored, maintained, reviewed/controlled and archived/destroyed as needed. All the activities are management concerns. Explicit service contracts may be stored in specialized repositories that provide appropriate level of security.

- 3367 Management of the service interfaces is based on several management policies that regulate
- availability of interfaces specified in the service contracts,
- accessibility of interfaces,

3371

- procedures for interface changes,
 - interface versions as well as the versions of all parts of the interfaces,
- traceability of the interfaces and their versions back to the service description document.

Management of the SLA is integral to the management of service monitoring and operational service behavior at run-time. An SLA usually enumerates service characteristics and expected performances of the service. Since an SLA carries the connotation of a "promise", monitoring is needed to know if the promise is being kept. Existence of an SLA itself does not guarantee that the consumer will be provided with the service level specified in the service contract.

The use of an SLA in a SOA ecosystem can be wider than just an agreement on technical performances. An SLA may contain remedies for situations where the promised service cannot be maintained, or the real world effect cannot be achieved due to developments subsequent to the agreement. A service consumer that acts accordingly to realize the real world effect may be compensated for the breach of the SLA if the effect is not realized.

3383 Management of the SLA includes, among others, policies to change, update, and replace the SLA. This 3384 aspect concerns service Execution Context because the business logic associated with a defined 3385 interface may differ in different Execution Contexts and affect the overall performance of the service.

3386 **5.3.4.3 Policies**

"Although provision of management capabilities enables a service to become manageable, the extent and
degree of permissible management are defined in management policies that are associated with the
services. Management policies are used to define the obligations for, and permissions to, managing the
service" [WSA]. Management policies, in essence, are the realization of governing rules and regulations.
As such, some management policies may target services while other policies may target the management
of the services.

In practice, a policy without any means of enforcing it is vacuous. In the case of management policy, we rely on a management infrastructure to realize and enforce management policy.

3395 5.3.4.4 Service Description and Management

The service description identifies several management objects such as a set of service interfaces and related set of SLAs. Service behavioral characteristics and performances specified in the SLA depend on the interface type and its Execution Context. In the service description, a service consumer can find references to management policies, SLA metrics, and the means of accessing measured values that together increase assurance in the service quality. At the same time, service description is an artifact that needs to be managed.

In the SOA ecosystem, the service description is the assembled information that describes the service but
it may be reported or displayed in different presentations. While each separate version of the service has
one and only one service description, different categories of service consumers may focus their interests
on different aspects of the service description. Thus, the same service description may be displayed not
only in different languages but also with different cultural and professional accents in the content.

New service description may be issued to reflect changes and update in the service. If the change in the
service does not affect its service description, the new service version may have the same service
description as the previous version except for the updated version identifier. For example, a service
description may stay the same if bugs were fixed in the service. However, if a change in the service

3411 influences any aspects of the service quality that can affect the real world effect resulting from

- 3412 interactions with the service, the service description must reflect this change even if there are no changes
- to the service interface.
- 3414 Management of service description and related explicit service contracts is essential for delivery of the 3415 service to the consumer satisfaction. This management can also prevent business problems rooted in
- 3416 poor communication between the service consumers and the service providers.

Thus, management of service description contains, among others, management of the service description
presentations, the life-cycles of the service descriptions, service description distribution practices and
storage of the service descriptions and related service contracts. Collections of service descriptions in
the enterprise may manifest a need for specialised registries and/or repositories. Depending on the
enterprise policies, an allocation of purposes and duties of registries and repositories may vary but this
topic is beyond the current scope.

3423 5.3.5 Management for Monitoring and Reporting

The successful application of management relies on the monitoring and reporting aspects of management to enable the control aspect. Monitoring in the context of management consists of measuring values of managed aspects and evaluating that measurement in relationship to some expectation. Monitoring in a SOA ecosystem is enabled through the use of mechanisms by resources for exposing managed aspects. In the SOA framework, this mechanism may be a service for obtaining the measurement. Alternatively, the measurement may be monitored by means of event generation containing updated values of the managed aspect.

Approaches to monitoring may use a polling strategy in which the measurements are requested from
resources in periodic intervals, in a pull strategy in which the measurements are requested from
resources at random times, or in a push strategy in which the measurements are supplied by the resource
without request. The push strategy can be used in a periodic update approach or in an "update on
change" approach. Management services must be capable of handling these different approaches to
monitoring.

3437 Reporting is the complement to monitoring. Where monitoring is responsible for obtaining measurements, 3438 reporting is responsible for distributing those measurements to interested stakeholders. The separation 3439 between monitoring and reporting is made to include the possibility that data obtained through monitoring 3440 might not be used until an event impacting the ecosystem occurs or the measurement requires further 3441 processing to be useful. In the SOA framework, reporting is provided using services for requesting 3442 measurement reports. These reports may consist of raw measurement data, formatted collections of data, 3443 or the results of analysis performed on measurement data from collections of different managed aspects. 3444 Reporting is also used to support logging and auditing capabilities, where the reporting mechanisms create log or audit entries. 3445

3446 **5.3.6 Management for Infrastructure**

All of the properties, policies, interactions, resources, and management are only possible if a SOA
ecosystem infrastructure provides support for managed capabilities. Each managed capability imposes
different requirements on the capabilities supplied by the infrastructure in SOA ecosystem and requires
that those capabilities be usable as services or at the very least be interoperable.

- 3451 While not providing a full list of infrastructural elements of a SOA ecosystem, we list some examples here:
- 3452 1. Registries and repositories for services, policies, and related descriptions and contracts
- 3453 2. Synchronous and asynchronous communication channels for service interactions (e.g., network, e-mail, message routing with ability of mediating transport protocols, etc.)
- 3455 3. Recovery capabilities
- 3456 4. Security controls
- 3457 A SOA ecosystem infrastructure, enabling service management, should also support:
- 3458 1. Management enforcement and control means
- 3459 2. Monitoring and SLA validation controls
- 3460 3. Testing and Reporting capabilities

3461 The combination of manageability capabilities and infrastructure elements constitutes a certain level of

3462 SOA management maturity. While several maturity models exist, this topic is out of the scope of the 3463 current document.

3464 **5.3.7 Architectural Implication of the Management Model**

3465 **5.4 SOA Testing Model**

3466 Testing for SOA combines the typical challenges of software testing and certification with the additional 3467 needs of accommodating the distributed nature of the resources, the greater access of a more unbounded consumer population, and the desired flexibility to create new solutions from existing 3468 3469 components over which the solution developer has little if any control. The purpose of testing is to demonstrate a required level of reliability, correctness, and effectiveness that enable prospective 3470 3471 consumers to have adequate confidence in using a service. Adequacy is defined by the consumer based 3472 on the consumer's needs and context of use. Absolute correctness and completeness cannot be proven 3473 by testing; however, for SOA, it is critical for the prospective consumer to know what testing has been 3474 performed, how it has been performed, and what were the results.

3475 **5.4.1 Traditional Software Testing as Basis for SOA Testing**

- 3476 SOA services are largely software artifacts and can leverage the body of experience that has evolved 3477 around software testing. IEEE-829 **[IEEE-829]** specifies the basic set of software test documents while 3478 allowing flexibility for tailored use. As such, the document structure can also provide guidance to SOA 3479 testing.
- 3480 IEEE-829 covers test specification and test reporting through use of the following document types:
- Test plan documenting the scope (what is to be tested, both which entity and what features of the entity), the approach (how it is tested), and the needed resources (who does the testing, for how long), with details contained in the:
 - *Test design specification*: features to be tested, test conditions (e.g. test cases, test procedures needed) and expected results (criteria for passing test); entrance and exit criteria
 - Test case specification: test data used for input and expected output
 - Test procedure specification: steps required to run the test, including any set-up preconditions
 - Test item transmittal to identify the test items being transmitted for testing
- Test log to record what occurred during test, i.e. which tests run, who ran, what order, what
 happened
- *Test incident report* to capture any event that happened during test which requires further investigation
- Test summary as a management report summarizing test run and results, conclusions
- In summary, IEEE-829 captures (1) what was tested, (2) how it was tested, e.g. the test procedure used,
 and (3) the results of the test.

3496 5.4.1.1 Types of Testing

3484

3485

3486

3487

3488

- There are numerous aspects of testing that, in total, work to establish that an entity is (1) built as required per policies and related specifications prescribed by the entity's owner, and (2) delivers the functionality required by its intended users. This is often referred to as verification and validation.
- Policies, as described in Section 4.4, that are related to testing may prescribe but are not limited to the business processes to be followed, the standards with which an implementation must comply, and the qualifications of and restrictions on the users. In addition to the functional requirements prescribing what an entity does, there may also be non-functional performance and/or quality metrics that state how well the entity does it. The relation of these policies to SOA testing is discussed further below.
- The identification of policies is the purview of governance (section 5.1) and the assuring of compliance (including response to noncompliance) with policies is a matter for management (section 5.3).

3507 5.4.1.2 Range of Test Conditions

Test conditions and expected responses are detailed in the test case specification. The test conditions should be designed to cover the areas for which the entity's response must be documented and may include: • nominal conditions

3513

3514

3515

3516

- boundaries and extremes of expected conditions
 - breaking point where the entity has degraded below a certain level or has otherwise ceased effective functioning
 - random conditions to investigate unidentified dependencies among combinations of conditions
 - errors conditions to test error handling

The specification of how each of these conditions should be tested for SOA resources, including the infrastructure elements of the SOA ecosystem, is beyond the scope of this document but is an area that evolves along with operational SOA experience.

3520 5.4.1.3 Configuration Management of Test Artifacts

The test item transmittal provides an unambiguous identification of the entity being tested, thus REQUIRING that the configuration of the entity is appropriately tracked and documented. In addition, the test documents (such as those specified by IEEE-829) MUST also be under a documented and appropriately audited configuration management process, as should other resources used for testing. The description of each artifact would follow the general description model as discussed in section 4.1.1.1; in particular, it would include a version number for the artifact and reference to the documentation describing the versioning scheme from which the version number is derived.

3528 **5.4.2 Testing and the SOA Ecosystem**

3529 Testing of SOA artifacts for use in the SOA ecosystem differs from traditional software testing for several 3530 reasons. First, a highly touted benefit of SOA is to enable unanticipated consumers to make use of 3531 services for unanticipated purposes. Examples of this could include the consumer using a service for a 3532 result that was not considered the primary one by the provider, or the service may be used in combination with other services in a scenario that is different from the one considered when designing for the initial 3533 3534 target consumer community. It is unlikely that a new consumer will push the services back to anything resembling the initial test phase to test the new use, and thus additional paradigms for testing are 3535 necessary. Some testing may depend on the availability of test resources made available as a service 3536 3537 outside the initial test community, while some testing is likely to be done as part of limited use in the operational setting. The potential responsibilities related to such "consumer testing" is discussed further 3538 3539 below.

3540 Secondly, in addition to consumers who interact with a service to realize the described real world effects. 3541 the developer community is also intended to be a consumer. In the SOA vision of reuse, the developer 3542 composes new solutions using existing services, where the existing services provides access to some 3543 desired real world effects that are needed by the new solution. The new solution is a consumer of the 3544 existing services, enabling repeated interactions with the existing services playing the role of reusable 3545 components. Note, those components are used at the locations where they individually reside and are not typically duplicated for the new solution. The new solution may itself be offered as a SOA service, and a 3546 3547 consumer of the service composition representing the new solution may be totally unaware of the 3548 component services being used. (See section 4.3.4 for further discussion on service compositions.)

Another difference from traditional testing is that the distributed, unbounded nature of the SOA ecosystem makes it unlikely to have an isolated test environment that duplicates the operational environment. A traditional testing approach often makes use of a test system that is identical to the eventual operational system but isolated for testing. After testing is successfully completed, the tested entity would be migrated to the operational environment, or the test environment may be delivered as part of the system to become operational. This is not feasible for the SOA ecosystem as a whole.

SOA services must be testable in the environment and under the conditions that can be encountered in the operational SOA ecosystem. As the ecosystem is in a state of constant change, so some level of testing is continuous through the lifetime of the service, leveraging utility services used by the ecosystem infrastructure to monitor its own health and respond to situations that could lead to degraded performance. This implies the test resources must incorporate aspects of the SOA paradigm, and a category of services may be created to specifically support and enable effective monitoring and continuous testing for resources participating in the SOA ecosystem.

- 3562 While SOA within an enterprise may represent a more constrained and predictable operational
- 3563 environment, the composability and unanticipated use aspects are highly touted within the enterprise.
- 3564 The expanded perspective on testing may not be as demanding within an enterprise but fuller
- 3565 consideration of the ecosystem enables the enterprise to be more responsive should conditions change.

3566 5.4.3 Elements of SOA Testing

IEEE-829 identifies fundamental aspects of testing, and many of these should carry over to SOA testing:
 in particular, the identification of what is to be tested, how it is to be tested, and by whom the testing is to
 be done. While IEEE-829 identifies a suggested document tree, the availability of these documents in the
 SOA ecosystem is discussed below.

3571 5.4.3.1 What is to be Tested

The focus of this discussion is the SOA service. It is recognized that the infrastructure components of any SOA environment are likely to also be SOA services and, as such, falls under the same testing guidance. Other resources that contribute to a SOA environment may not be SOA services, but are expected to satisfy the intent if not the letter of guidance presented here. Specific differences for such resources are as yet largely undefined and further elaboration is beyond the scope of the SOA-RAF.

The following discussion often focuses on a singular SOA service but it is implicit that any service may be a composite of other services. As such, testing the functionality of a composite service may effectively be testing an end-to-end business process that is being provided by the composite service. If new versions are available for the component services, appropriate end-to-end testing of the composite may be required in order to verify that the composite functionality is still adequately provided. The level of required testing of an updated composite depends on policies of those providing the service, policies of those using the service, and mission criticality of those depending on the service results.

The SOA service to be tested MUST be unambiguously identified as specified by its applicable configuration management scheme. Specifying such a scheme is beyond the scope of the SOA-RAF other than to say the scheme should be documented and itself under configuration management.

3587 **5.4.3.1.1 Origin of Test Requirements**

3589

3590

3591

3592

3593

- 3588 In the Service Description model (Figure 13), the aspects of a service that need to be described are:
 - the service functionality and technical assumptions that underlie the functionality;
 - the policies that describe conditions of use;
 - the service interface that defines information exchange with the service;
 - service reachability that identifies how and where message exchange is to occur; and
 - metrics access for any participant to have information on how a service is performing.
- 3594 Service testing must provide adequate assurance that each of these aspects is operational as defined.

The information in the service description comes from different sources. The functionality is defined through whatever process identifies needs and the community for which these needs are addressed. The process may be ad hoc as serves the prospective service owner or strictly governed, but defining the functionality is an essential first step in development. It is also an early and ongoing focus of testing to ensure the service accurately reflects the described functionality and the described functionality accurately addresses the consumer needs.

- 3601 Policies define the conditions of development and conditions of use for a service and are typically 3602 specified as part of the governance process. Policies constraining service development, such as coding 3603 standards and best practices, require appropriate testing and auditing during development to ensure 3604 compliance. While the governance process identifies development policies, these are likely to originate 3605 from the technical community responsible for development activities. Policies that define conditions of 3606 use often define business practices that service owners and providers or those responsible for the SOA 3607 infrastructure want followed. These policies are initially tested during service development and are 3608 continuously monitored during the operational lifetime of the service.
- 3609 The testing of the service interface and service reachability are often related but essentially reflect 3610 different motivations and needs. The service interface is specified as a joint product of the service

- 3611 owners and providers who define service functionality, the prospective consumer community, the service
- 3612 developer, and the governance process. The semantics of the information model must align with the
- 3613 semantics of those who consume the service in order for there to be meaningful exchange of information. 3614 The structure of the information is influenced by the consumer semantics and the requirements and
- 3614 The structure of the information is influenced by the consumer semantics and the requirements and 3615 constraints of the representation as interpreted by the service developer. The service process model that
- 3616 defines actions which can be performed against a service and any temporal dependencies derive from
- 3617 the defined functionality and may be influenced by the development process. Any of these constraints
- 3618 may be identified and expressed as policy through the governance process.
- 3619 Service reachability conditions are the purview of the service provider who identifies the service endpoint 3620 and the protocols recognized at the endpoint. These may be constrained by governance decisions on 3621 how endpoint addresses may be allocated and what protocols should be used.
- While the considerations for defining the service interface derive from several sources, testing of the service interface is more straightforward and isolated in the testing process. At any point where the interface is modified or exposes a new resource, the message exchange should be monitored both to ensure the message reaches its intended destination and it is parsed correctly once received. Once an interface has been shown to function properly, it is unlikely to fail later unless something fundamental to the service changes.
- 3628 The service interface is also tested when the service endpoint changes. Testing of the endpoint ensures 3629 message exchange can occur at the time of testing and the initial testing shows the interface is being processed properly at the new endpoint. Functioning of a service endpoint at one time does not 3630 3631 guarantee it is functioning at another time, e.g. the server with the endpoint address may be down, making testing of service reachability a continual monitoring function through the life of the service's use 3632 of the endpoint. Also, while testing of the service endpoint is a necessary and most commonly noted part 3633 3634 of the test regiment, it is not in itself sufficient to ensure the other aspects of testing discussed in this 3635 section.
- 3636 Finally, governance is impossible without the collection of metrics against which service behavior can be 3637 assessed. Metrics are also a key indicator for consumers to decide if a service is adequate for their 3638 needs. For instance, the average response time or the recent availability can be determining factors even 3639 if there are no rules or regulations promulgated through the governance process against which these 3640 metrics are assessed. The available metrics are a combination of those expected by the consumer 3641 community and those mandated through the governance process. The total set of metrics will evolve 3642 over time with SOA experience. Testing of the services that gather and provide access to the metrics will 3643 follow testing as described in this section, but for an individual service, testing will ensure that the metrics 3644 access indicated in the service description is accurate.
- The individual test requirements highlight aspects of the service that testing must consider but testing must establish more than isolated behavior. The emphasis is the holistic results of interacting with the service in the SOA environment. Recall that the execution context is the set of agreements between a consumer and a provider that define the conditions under which service interaction occurs. The agreements are expected to be predominantly the acceptance of the standard conditions as enumerated by the service provider, but it may include the identification of alternate conditions that will govern the interaction.
- For example, the provider may prefer a policy where it can sell the contact information of its consumers but will honor the request of a consumer to keep such information private. The identification of the alternate privacy policy is part of the execution context, and it is the application of and compliance with this policy that operational monitoring will attempt to measure. The collection of metrics showing this condition is indeed met when chosen is considered part of the ongoing testing of the service.
- 3657 Other variations in the execution context also require monitoring to ensure that different combinations of 3658 conditions perform together as desired. For example, if a new privacy policy takes additional resources to 3659 apply, this may affect quality of service and propagate other effects. These could not be tested during the 3660 original testing if the alternate policy did not exist at that time.

3661 5.4.3.1.2 Testing Against Non-Functional Requirements

- Testing against non-functional requirements constitutes testing of business usability of the service. In a marketplace of services, non-functional characteristics may be the primary differentiator between services that produce essentially the same real world effects.
- As noted in the previous section, non-functional characteristics are often associated with policies or other terms of use and may be collected in service level contracts offered by the service providers. Nonfunctional requirements may also reflect the network and hardware infrastructure that support communication with the service, and changes may impact quality of service. The service consumer and even the service provider may not be aware of all such infrastructure changes but the changes may manifest in shared states that impact the usability of the service.
- 3671 In general, a change in the non-functional requirements results in a change to the execution context, but 3672 as with any collection of information that constitutes a description, the execution context is unable to 3673 explicitly capture all non-functional requirements that may apply. A change in non-functional requirements, whether explicitly part of the execution context or an implicit contributor, may require 3674 3675 retesting of the service even if its functionality and the implementation of the functionality has not 3676 changed. Depending on the circumstances, retesting may require a formal recertifying of end-to-end 3677 behavior or more likely will be part of the continuous monitoring that applies throughout the service 3678 lifetime.

3679 5.4.3.1.3 Testing Content and the Interests of Consumers

- 3680 As noted in section 5.4.1.1, testing may involve verification of conformance with respect to policies and 3681 technical specifications and validation with respect to sufficiency of functionality to meet some prescribed 3682 use. It may also include demonstration of performance and quality aspects. For some of these items. 3683 such as demonstrating the business processes followed in developing the service or the use of standards in implementing the service, the testing or relevant auditing is done internal to the service development 3684 process and follows traditional software testing and quality assurance. If it is believed of value to 3685 potential consumers, information about such testing could be included in the service description. 3686 However, it is not required that all test or compliance artifacts be available to consumers, as many of the 3687 3688 details tested may be part of the opacity of the service implementation.
- 3689 Some aspects of the service being tested will reflect directly on the real world effects realized through 3690 interaction with the service. In these cases, it is more likely that testing results will be directly relevant to 3691 potential consumers. For example, if the service was designed to correspond to certain elements of a 3692 business process or that a certain workflow is followed, testing should verify that the real world effects 3693 reflect that the business process or workflow were satisfactorily captured.
- The testing may also need to demonstrate that specified conditions of use are satisfied. For example, policies may be asserted that require certain qualifications of or impose restrictions on the consumers who may interact with the service. The service testing must demonstrate that the service independently enforces the policies or it provides the required information exchanges with the SOA ecosystem so other resources can ensure the specified conditions.
- The completeness of the testing, both in terms of the features tested and the range of parameters for which response is tested, depends on the context of expected use: the more critical the use, the more complete the testing. There are always limits on the resources available for testing, if nothing else than the service must be available for use in a finite amount of time.
- This again emphasizes the need for adequate documentation to be available. If the original testing is very thorough, it may be adequate for less demanding uses in the future. If the original testing was more constrained, then well-documented test results establish the foundation on which further testing can be defined and executed.

3707 **5.4.3.2 How Testing is to be Done**

Testing should follow well-defined methodologies and, if possible, should reuse test artifacts that have
proven generally useful for past testing. For example, IEEE-829 notes that test cases are separated from
test designs to allow for use in more than one design and to allow for reuse in other situations. In the

- 3711 SOA ecosystem, description of such artifacts, as with description of a service, enables awareness of the 3712 item and describes how the artifact may be accessed or used.
- 3713 As with traditional testing, the specific test procedures and test case inputs are important so the tests are
- unambiguously defined and entities can be retested in the future. Automated testing and regression
- testing may be more important in the SOA ecosystem in order to re-verify a service is still acceptable
- 3716 when incorporated in a new use. For example, if a new use requires the services to deal with input
- 3717 parameters outside the range of initial testing, the tests could be rerun with the new parameters. If the 3718 testing resources are available to consumers within the SOA ecosystem, the testing as designed by test
- 3710 resulting resources are available to consumers within the SOA ecosystem, the testing as designed by tes 3719 professionals could be consumed through a service accessed by consumers, and their results could
- 3720 augment those already in place. This is discussed further in the next section.

3721 5.4.3.3 Who Performs the Testing

- As with any software, the first line of testing is unit testing done by software developers. It is likely that initial testing will be done by those developing the software but may also be done independently by other developers. For SOA development, unit testing is likely confined to a development sandbox isolated from the SOA ecosystem.
- 3726 SOA testing will differ from traditional software testing in that testing beyond the development sandbox
- 3727 must incorporate aspects of the SOA ecosystem, and those doing the testing must be familiar with both
- 3728 the characteristics and responses of the ecosystem and the tools, especially those available as services,
- to facilitate and standardize testing. Test professionals will know what level of assurance must be
- 3730 established as the exposure of the service to the ecosystem and ecosystem to the service increases
- towards operational status. These test professionals may be internal resources to an organization or may
 evolve as a separate discipline provided through external contracting.
- As noted above, it is unlikely that a complete duplicate of the SOA ecosystem will be available for isolated
- testing, and thus use of ecosystem resources will manifest as a transition process rather than a step
 change from a test environment to an operational one. This is especially true for new composite services
 that incorporate existing operational services to achieve the new functionality. The test professionals will
 need to understand the available resources and the ramifications of this transition.
- As with current software development, a stage beyond work by test professionals will make use of a select group of typical users, commonly referred to as beta testers, to report on service response during typical intended use. This establishes fitness by the consumers, providing final validation of previously
- 3741 verified processes, requirements, and final implementation.
- In traditional software development, beta testing is the end of testing for a given version of the software.
 However, although the initial test phase can establish an appropriate level of confidence consistent with
 the designed use for the initial target consumer community, the operational service will exist in an
 evolving ecosystem, and later conditions of use may differ from those thought to be sufficient during the
 initial testing. Thus, operational monitoring becomes an extension of testing through the service lifetime.
 This continuous testing will attempt to ensure that a service does not consume an inordinate amount of
 ecosystem resources or display other behavior that degrades the ecosystem, but it will not undercover
- 3749 functional errors that may surface over time.
- 3750 As with any software, it is the responsibility of the consumers to consider the reasonableness of solutions 3751 in order to spot errors in either the software or the way the software is being used. This is especially
- important for consumers with unanticipated uses that may go beyond the original test conditions. It is
- unlikely the consumers will initiate a new round of formal testing unless the new use requires a
 significantly higher level of confidence in the service. Rather the consumer becomes a new extension to
- 3755 the testing regiment. Obvious testing would include a sanity check of results during the new use.
- 3756 However, if the details of legacy testing are associated with the service through the service description
- 3757 and if testing resources are available through automated testing services, then the new consumers can
- 3758 rerun and extend previous testing to include the extended test conditions. If the test results are
- acceptable, these can be added to the documentation of previous results and become the extended basis
- 3760 for future decisions by prospective consumers on the appropriateness of the service. If the results are not
- acceptable or in some way questionable, the responsible party for the service or testing professionals canbe brought in to decide if remedial action is necessary.

3763 5.4.3.4 How Testing Results are Reported

For any SOA service, an accurate reporting of the testing a service has undergone and the results of the testing is vital to consumers deciding whether a service is appropriate for intended use. Appropriateness may be defined by a consumer organization and require specific test regiments culminating in a certification; appropriateness could be established by accepting testing and certifications that have been conferred by others.

3769 The testing and certification information should be identified in the service description. Referring to the general description model of Figure 11, tests conducted by or under a request from the service owner 3770 (see ownership in section 3.1.3) would be captured under Annotations from Owners. Testing done by 3771 3772 others, such as consumers with unanticipated uses, could be associated through Annotations from 3rd 3773 Parties. The annotations should clearly indicate what was tested, how the testing was done, who did the testing, and the testing results. The clear description of each of these artifacts and of standardized 3774 testing protocols for various levels of sophistication and completeness of testing would enable a common 3775 3776 understanding and comparison of test coverage. It will also make it more straightforward to conduct and 3777 report on future testing, facilitating the maintenance of the service description.

Consumer testing and the reporting of results raises additional issues. While stating who did the testing is mandatory, there may be formal requirements for authentication of the tester to ensure traceability of the testing claims. In some circumstances, persons or organizations would not be allowed to state testing claims unless the tester was an approved entity. In other cases, ensuring the tester had a valid email may be sufficient. In either case, it would be at the discretion of the potential consumer to decide what level of authentication was acceptable and which testers are considered authoritative in the context of their anticipated use.

Finally, in a world of openly shared information, we would see an ever-expanding set of testing
information as new uses and new consumers interact with a service. In reality, these new uses may
represent proprietary processes or classified use that should only be available to authorized parties.
Testing information, as with other elements of description, may require special access controls to ensure

3788 Testing information, as with other elements of description, may require special access controls to ensure 3789 appropriate access and use.

3790 5.4.4 Testing SOA Services

Testing of SOA services should be consistent with the SOA paradigm. In particular, testing resources 3791 3792 and artifacts should be visible in support of service interaction between providers and consumers, where 3793 here the interaction is between the testing resource and the tester. In addition, the idea of opacity of the 3794 implementation should limit the details that need to be available for effective use of the test resources. 3795 Testing that requires knowledge of the internal structure of the service or its underlying capability should 3796 be performed as part of unit testing in the development sandbox, and should represent a minimum level 3797 of confidence before the service begins its transition to further testing and eventual operation in the SOA 3798 ecosystem.

3799 5.4.4.1 Progression of SOA Testing

Software testing is a gradual exercise going from micro inspection to testing macro effects. The first step in testing is likely the traditional code reviews. SOA considerations would account for the distributed nature of SOA, including issues of distributed security and best practices to ensure secure resources. It would also set the groundwork for opacity of implementation, hiding programming details and simplifying the use of the service.

Code review is likely followed by unit testing in a development sandbox isolated from the operational environment. The unit testing is done with full knowledge of the service internal structure and knowledge of resources representing underlying capabilities. It tests the interface to ensure exchanged messages are as specified in the service description and the messages can be parsed and interpreted as intended. Unit testing also verifies intended functionality and that the software has dealt correctly with internal dependencies, such as structure of a file system or access to other dedicated resources.

Some aspects of unit testing require external dependencies be satisfied, and this is often done using
 mock objects to substitute for the external resources. In particular, it will likely be necessary to include

3813 mocks of existing operational services, both those provided as part of the SOA infrastructure and services

3814 from other providers.

3815 Service Mock

- 3816A service mock is an entity that mimics some aspect of the performance of an operational service3817without committing to the real world effects that the operational service would produce.
- 3818 Mocks are discussed in detail in sections 5.4.4.3 and 5.4.4.4.

3819 After unit testing has demonstrated an adequate level of confidence in the service, the testing must 3820 transition from the tightly controlled environment of the development sandbox to an environment that 3821 more clearly resembles the operational SOA ecosystem or, at a minimum, the intended enterprise. While 3822 sandbox testing will use simple mocks of some aspects of the SOA environment, such as an interface to 3823 a security service without the security service functionality, the dynamic nature of SOA makes a full 3824 simulation infeasible to create or maintain. This is especially true when a new composite service makes use of operational services provided by others. Thus, at some point before testing is complete, the 3825 3826 service will need to demonstrate its functionality by using resources and dealing with conditions that only 3827 exist in the full ecosystem or the intended enterprise. Some of these resources may still provide test interfaces -- more on this below -- but the interfaces will be accessible using the SOA environment and 3828 3829 not just implemented for the sandbox.

3830 At this stage, the opacity of the service becomes important as the details of interacting with the service 3831 now rely on correct use of the service interface and not knowledge of the service internals. The workings 3832 of the service will only be observable through the real world effects realized through service interactions 3833 and external indications that conditions of use, such as user authentication, are satisfied. Monitoring the 3834 behavior of the service will depend on service interfaces that expose internal monitoring or provide 3835 required information to the SOA infrastructure monitoring function. The monitoring required to test a new service is likely to have significant overlap with the monitoring the SOA infrastructure includes to monitor 3836 its own health and to identify and isolate behavior outside of acceptable bounds. This is exactly what is 3837 3838 needed as part of service testing, and it is reasonable to assume that the ecosystem transition includes 3839 use of operational monitoring rather than solely dedicated monitoring for each service being tested.

Use of SOA monitoring resources during the explicit testing phase sets the stage for monitoring and alevel of continual testing throughout the service lifetime.

3842 **5.4.4.2 Testing Traditional Dependencies vs. Service Interactions**

3843 A SOA service is not required to make use of other operational services beyond what may be required for monitoring by the ecosystem infrastructure. The service can implement hardcoded dependencies which 3844 3845 have been tested in the development sandbox through the use of dedicated mocks. While coordination 3846 may be required with real data sources during integration testing, the dependencies can be constrained to 3847 things that can be tested in a more traditional manner. Policies can also be set to restrict access to pre-3848 approved users, and thus the question of unanticipated users and unanticipated uses can be eliminated. 3849 Operational readiness can be defined in terms of what can be proven in isolated testing. While all this 3850 may provide more confidence in the service for its designed purpose, such a service will not fully 3851 participate in the benefits or challenges of the ecosystem. This is akin to filling a swimming pool with sea 3852 water and having someone in the pool say they are swimming in the ocean.

3853 In considering the testing needed for a fully participating service, consider the example of a new 3854 composite service that combines the real world effects and complies with the conditions of use of five 3855 existing operational services. The developer of the composite service does not own any of the 3856 component services and has limited, if any, ability to get the distributed owners to do any customization. 3857 The developer also is limited by the principle of opacity to information comprising the service description, 3858 and does not know internal details of the component services. The developer of the composite service 3859 must use the component services as they exist as part of the SOA environment, including what is 3860 provided to support testing by new users. This introduces requirements for what is needed in the way of service mocks. 3861

3862 **5.4.4.3 Use of Service Mocks**

3863 Service mocks enables the tested service to respond to specific features of an operational service that is 3864 being used as a component. It allows service testing to proceed without needing access to or with only 3865 limited engagement with the component service. Mocks can also mimic difficult to create situations for which it is desired to test the new service response. For composite services using multiple component 3866 services, mocks may be used in combination to function for any number of the components. Note, when 3867 3868 using service mocks, it is important to remember that it is not the component service that is being tested 3869 (although anomalous behavior may be uncovered during testing) but the use of the component in the new 3870 composite.

Individual service mocks can emphasize different features of the component service they represent but
any given mock does not have to mimic all features. For example, a mock of the service interface can
echo a sent message and demonstrate the message is reaching its intended destination. A mock could
go further and parse the sent message to demonstrate the message not only reached its destination but

- was understood. As a final step, the mock could report back what actions would have been taken by the
 component service and what real world effects would result. If the response mimicked the operational
 response, functional testing could proceed as if the real world effect actually occurred.
- There are numerous ways to provide mock functionality. The service mock could be a simulation of the operational service and return simulated results in a realistic response message or event notification. It is also possible for the operational service to act as its own mock and simply not execute the commit stage of its functionality. The service mock could use a combination of simulation and service action without commit to generate a report of what would have occurred during the defined interaction with the operational service.
- As the service proceeds through testing, mocks should be systematically replaced by the component
 resources accessed through their operational interfaces. Before beta testing begins, end-to-end testing,
 i.e. proceeding from the beginning of the service interaction to the resulting real world results, should be
 accomplished using component resources via their operational interfaces.

3888 5.4.4.4 Providers of Service Mocks

In traditional testing, it is often the test professionals who design and develop the mocks, but in the distributed world of SOA, this may not be efficient or desirable.

- In the development sandbox, it is likely the new service developer or test professionals working with the developer will create mocks adequate for unit testing. Given that most of this testing is to verify the new service is performing as designed, it is not necessary to have high fidelity models of other resources being accessed. In addition, given opacity of SOA implementation, the developer of the new service may not have sufficient detailed knowledge of a component service to build a detailed mock of the component service functionality. Sharing existing mocks at this stage may be possible but the mocks would need to be implemented in the sandbox, and for simple models it is likely easier to build the mock from scratch.
- As testing begins its transition to the wider SOA environment, mocks may be available as services. For existing resources, it is possible that an Open Source model could evolve where service mocks of available functions can be catalogued and used during initial interaction of the tested service and the operational environment. Widely used functions may have numerous service mocks, some mimicking detailed conditions within the SOA infrastructure. However, the Open Source model is less likely to be sufficient for specialty services that are not widely used by a large consumer community.
- 3904 The service developer is probably best qualified for also developing more detailed service mocks or for 3905 mock modes of operational services. This implies that in addition to their operational interfaces, services 3906 will routinely provide test interfaces to enable service mocks to be used as services. As noted above, a 3907 new service developer wanting to build a mock of component services is limited to the description 3908 provided by the component service developer or owner. The description typically will detail real world 3909 effects and conditions of use but will not provide implementation details, some of which may be 3910 proprietary. Just as important in the SOA ecosystem, if it becomes standard protocol for developers to 3911 create service mocks of their own services, a new service developer is only responsible for building his 3912 own mocks and can expect other mocks to be available from other developers. This reduces duplication 3913 of effort where multiple developers would be trying to build the same mocks from the same insufficient

- information. Finally, a service developer is probably best qualified to know when and how a service mockshould be updated to reflect modified functionality or message exchange.
- 3916 It is also possible that testing organizations will evolve to provide high-fidelity test harnesses for new
- 3917 services. The harnesses would allow new services to plug into a test environment and would facilitate
- 3918 accessing mocks of component services. However, it will remain a constant challenge for such
- 3919 organizations to capture evolving uses and characteristics of service interactions in the real SOA
- 3920 environment and maintain the fidelity and accuracy of the test systems.

3921 5.4.4.5 Fundamental Questions for SOA Testing

3924

3925 3926

3927

3946

3947

3948

3949

3950

- In order for the transition to the SOA operational environment to proceed, it is necessary to answer twofundamental questions:
 - Who provides what testing resources for the SOA operational environment, e.g. mocks of interfaces, mocks of functionality, monitoring tools?
 - What testing needs to be accomplished before operational environment resources can be accessed for further testing?
- The discussion in section 5.4.4.4 notes various levels of sophistication of service mocks and different communities are likely to be responsible for different levels. Section 5.4.4.4 advocates a significant role for service developers, but there needs to be community consensus that such mocks are needed and that service developers will agree to fulfilling this role. There is also a need for consensus as to what tools should be available as services from the SOA infrastructure.
- As for use of the service mocks and SOA environment monitoring services, practical experience is needed upon which guidelines can be established for when a new service has been adequately tested to proceed with a greater level of exposure with the SOA environment. Malfunctioning services could cause serious problems if they cannot be identified and isolated. On the other hand, without adequate testing under SOA operational conditions, it is unlikely that problems can be uncovered and corrected before they reach an operational stage.
- As noted in section 5.4.4.2, some of these questions can be avoided by restricting services to more
 traditional use scenarios. However, such restriction will limit the effectiveness of SOA use and the result
 will resemble the constraints of traditional integration activities we are trying to move beyond.

3942 **5.4.5 Architectural Implications for SOA Testing**

- 3943 The discussion of SOA Testing indicates numerous architectural implications on the SOA ecosystem:
- The distributed, boundary-less nature of the SOA ecosystem makes it infeasible to create and maintain a single mock of the entire ecosystem to support testing activities.
 - A standard suite of monitoring services needs to be defined, developed, and maintained. This should be done in a manner consistent with the evolving nature of the ecosystem.
 - Services should provide interfaces that support access in a test mode.
 - Testing resources must be described and their descriptions must be catalogued in a manner that enables their discovery and access.
- Guidelines for testing and ecosystem access need to be established and the ecosystem must be able to enforce those guidelines asserted as policies.
- Services should be available to support automated testing and regression testing.
- Services should be available to facilitate updating service description by anyone who has
 performed testing of a service.

3956 6 Conformance

This Reference Architecture Framework is an abstract architectural description of Service Oriented
 Architecture, which means that it is especially difficult to construct tests for conformance to the
 architecture. In addition, conformance to an architectural specification does not, by itself, guarantee any
 form of interoperability between multiple implementations.

However, it *is* possible to decide whether or not a given architecture is conformant to an architectural description such as this one. In discussions of conformance we use the term **target architecture** to identify the (typically concrete) architecture that may be viewable as conforming to the abstract principles outlined in this document.

3965 Target Architecture

3966A target architecture is an architectural description of a system that is intended to be viewed as3967conforming to the SOA-RAF.

3968 While we cannot guarantee interoperability between target architectures (or more specifically between 3969 applications and systems residing within the ecosystems of those target architectures), interoperability 3970 between target architectures is promoted by conformance to this Reference Architecture Framework as it 3971 reduces the semantic impedance mismatch between the different ecosystems.

- 3972 The primary measure of conformance is whether given concepts as described in document have
- 3973 corresponding concepts in the target architecture. Such a correspondence MUST honor the relationships 3974 identified within this document for the target architecture to be considered conforming.
- 3975 For example, in Section 3.1.3.1 we identify resource as a key concept. A resource is associated with an
- 3976 owner and a number of identifiers. For a target architecture to conform to the SOA-RAF, it must be

3977 possible to find corresponding concepts of resource, identifier and owner within the target architecture:
 3978 say *entity*, *token* and *user*. Furthermore, the relationships between *entity*, *token* and *user* MUST mirror
 3979 the relationships between resource, identifier and owner appropriately.

3980 Clearly, such correspondence is simpler if the terminology within the target architecture is identical to that 3981 in the SOA-RAF. But so long as the 'graph' of concepts and relationships is consistent, that is all that is

- 3982 required for the target architecture to conform to this Reference Architecture Framework.
- 3983 [EDITOR'S NOTE: The conformance section is not complete]

3984

3985 A. Acknowledgements

- The following individuals have participated in the work of the technical committee responsible for creation
- 3987 of this specification and are gratefully acknowledged:

3988 Participants:

- Chris Bashioum, MITRE Corporation 3989 Rex Brooks. Individual Member 3990 3991 Peter Brown, Individual Member 3992 Scott Came, Search Group Inc. 3993 Joseph Chiusano, Booz Allen Hamilton 3994 Robert Ellinger, Northrop Grumman Corporation 3995 David Ellis, Sandia National Laboratories Jeff A. Estefan, Jet Propulsion Laboratory 3996 3997 Don Flinn, Individual Member Anil John, Johns Hopkins University 3998 3999 Ken Laskey, MITRE Corporation Boris Lublinsky, Nokia Corporation 4000 Francis G. McCabe, Individual Member 4001 Christopher McDaniels, USSTRATCOM 4002 4003 Tom Merkle, Lockheed Martin Corporation 4004 Jyoti Namjoshi, Patni Computer Systems Ltd. 4005 Duane Nickull, Adobe Inc. 4006 James Odell, Associate Michael Poulin, Fidelity Investments 4007 4008 Michael Stiefel, Associate 4009 Danny Thornton, Northrop Grumman Timothy Vibbert, Lockheed Martin Corporation 4010 Robert Vitello, New York Dept. of Labor 4011

4099 C. The Unified Modeling Language, UML

Figure 44 illustrates an annotated example of a UML class diagram that is used to represent a visual model depiction of the Resources Model in the *Participation in a SOA Ecosystem* view.

4102

4103 Figure 44 - Example UML class diagram—Resources

4104 Lines connecting boxes (classifiers) represent associations between things. An association has two roles

4105 (one in each direction). A role can have cardinality, for example, one or more ("1..*") stakeholders own

4106 zero or more ("0..*) resources. The role from classifier A to B is labeled closest to B, and vice versa, for 4107 example, the role between resource to Identity can be read as resource embodies Identity, and Identity 4108 denotes a resource.

4109 Mostly, we use named associations, which are denoted with a verb or verb phrase associated with an

4110 arrowhead. A named association reads from classifier A to B, for example, one or more stakeholders

- 4111 owns zero or more resources. Named associations are a very effective way to model relationships
- 4112 between concepts.

4113 An open diamond (at the end of an association line) denotes an aggregation, which is a part-of

4114 relationship, for example, Identifiers are part of Identity (or conversely, Identity is made up of Identifiers).

4115 A stronger form of aggregation is known as composition, which involves using a filled-in diamond at the

4116 end of an association line (not shown in above diagram). For example, if the association between Identity

4117 and Identifier were a composition rather than an aggregation as shown, deleting Identity would also

4118 delete any owned Identifiers. There is also an element of exclusive ownership in a composition 4119 relationship between classifiers, but this usually refers to specific instances of the owned classes

4120 (objects).

4121 This is by no means a complete description of the semantics of all diagram elements that comprise a

4122 UML class diagram, but rather is intended to serve as an illustrative example for the reader. It should be

4123 noted that the SOA-RAF utilizes additional class diagram elements as well as other UML diagram types

4124 such as sequence diagrams and component diagrams. The reader who is unfamiliar with the UML is

4125 encouraged to review one or more of the many useful online resources and book publications available

4126 describing UML (see, for example, www.uml.org).

4127 **D. Critical Factors Analysis**

4128 A critical factors analysis (CFA) is an analysis of the key properties of a project. A CFA is analyzed in 4129 terms of the goals of the project, the critical factors that will lead to its success and the measurable 4130 requirements of the project implementation that support the goals of the project. CFA is particularly 4131 suitable for capturing guality attributes of a project, often referred to as "non-functional" or "other-than-

- 4131 suitable for capturing quality attributes of a project, ofter referred to as non-functional of other-man-4132 functional" requirements: for example, security, scalability, wide-spread adoption, and so on. As such,
- 4133 CFA complements rather than attempts to replace other requirements capture techniques.

4134 **D.1 Goals**

4135 A goal is an overall target that you are trying to reach with the project. Typically, goals are hard to 4136 measure by themselves. Goals are often directed at the potential consumer of the product rather than the

4137 technology developer.

4138 D.2 Critical Success Factors

4139 A critical success factor (CSF) is a property, sub-goal that directly supports a goal and there is strong 4140 belief that without it the goal is unattainable. CSFs themselves are not necessarily measurable in

4141 themselves.

4142 **D.3 Requirements**

4143 A requirement is a specific measurable property that directly supports a CSF. The key here is

4144 measurability: it should be possible to unambiguously determine if a requirement has been met. While

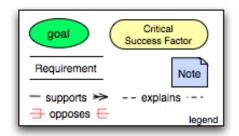

goals are typically directed at consumers of the specification, requirements are focused on technical

4146 aspects of the specification.

4147 **D.4 CFA Diagrams**

4148 It can often be helpful to illustrate graphically the key concepts and relationships between them. Such

- 4149 diagrams can act as effective indices into the written descriptions of goals etc., but is not intended to 4150 replace the text.
- 4151 The legend:
- 4152

4153

4154 illustrates the key elements of the graphical notation. Goals are written in round ovals, critical success

- factors are written in round-ended rectangles and requirements are written using open-ended rectangles.
 The arrows show whether a CSF/goal/requirement is supported by another element or opposed by it. This
- 4157 highlights the potential for conflict in requirements.

4158

4159 E. Relationship to other SOA Open Standards

The white paper "Navigating the SOA Open Standards Landscape Around Architecture" issued jointly by
OASIS, OMG, and The Open Group [SOA-NAV] was written to help the SOA community at large
navigate the myriad of overlapping technical products produced by these organizations with specific
emphasis on the "A" in SOA, i.e., Architecture.

4164 The white paper explains and positions standards for SOA reference models, ontologies, reference 4165 architectures, maturity models, modeling languages, and standards work on SOA governance. It outlines

where the works are similar, highlights the strengths of each body of work, and touches on how the work
can be used together in complementary ways. It is also meant as a guide to users for selecting those
specifications most appropriate for their needs.

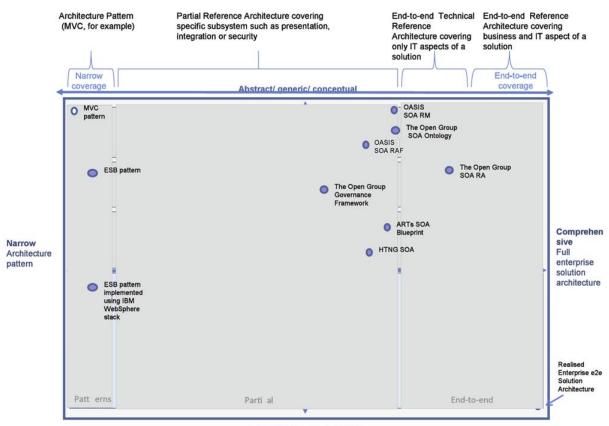

4169 While the understanding of SOA and SOA Governance concepts provided by these works is similar, the

4169 while the understanding of SOA and SOA Governance concepts provided by these works is similar, the 4170 evolving standards are written from different perspectives. Each specification supports a similar range of

4171 opportunity, but has provided different depths of detail for the perspectives on which they focus. Although

- the definitions and expressions may differ, there is agreement on the fundamental concepts of SOA andSOA Governance.
- 4174 The following is a summary taken from **[SOA-NAV]** of the positioning and guidance on the specifications:
- 4175
 The OASIS Reference Model for SOA (SOA RM) is the most abstract of the specifications positioned. It is used for understanding core SOA concepts
- The Open Group SOA Ontology extends, refines, and formalizes some of the core concepts of the SOA RM. It is used for understanding core SOA concepts and facilitates a model-driven approach to SOA development.
- The OASIS Reference Architecture Foundation for SOA (this document) is an abstract, foundational reference architecture addressing a broader ecosystem viewpoint for building and interacting within the SOA paradigm. It is used for understanding different elements of SOA, the completeness of SOA architectures and implementations, and considerations for reaching across ownership boundaries where there is no single authoritative entity for SOA and SOA governance.
- The Open Group SOA Reference Architecture is a layered architecture from consumer and provider perspective with cross cutting concerns describing these architectural building blocks and principles that support the realizations of SOA. It is used for understanding the different elements of SOA, deployment of SOA in enterprise, basis for an industry or organizational reference architecture, implication of architectural decisions, and positioning of vendor products in a SOA context.
- The Open Group SOA Governance Framework is a governance domain reference model and method. It is for understanding SOA governance in organizations. The OASIS Reference Architecture for SOA Foundation contains an abstract discussion of governance principles as applied to SOA across boundaries
- The Open Group SOA Integration Maturity Model (OSIMM) is a means to assess an organization's maturity within a broad SOA spectrum and define a roadmap for incremental adoption. It is used for understanding the level of SOA maturity in an organization
- The Object Management Group SoaML Specification supports services modeling UML
 extensions. It can be seen as an instantiation of a subset of the Open Group RA used for
 representing SOA artifacts in UML.

Fortunately, there is a great deal of agreement on the foundational core concepts across the many independent specifications and standards for SOA. This could be best explained by broad and common experience of users of SOA and its maturity in the marketplace. It also provides assurance that investing in SOA-based business and IT transformation initiatives that incorporate and use these specifications and standards helps to mitigate risks that might compromise a successful SOA solution.
