Understand update expression order

The following code example shows how to understand update expression order.

- Learn how DynamoDB processes update expressions.
- Understand the order of operations in update expressions.
- Avoid unexpected results by understanding expression evaluation.

SDK for Java 2.x

Demonstrate update expression order using AWS SDK for Java 2.x.

```
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.GetItemRequest;
import software.amazon.awssdk.services.dynamodb.model.GetItemResponse;
import software.amazon.awssdk.services.dynamodb.model.ReturnValue;
import software.amazon.awssdk.services.dynamodb.model.UpdateItemRequest;
import software.amazon.awssdk.services.dynamodb.model.UpdateItemResponse;

import java.util.HashMap;
import java.util.Map;

    /**
     * Demonstrates the effect of update expression order.
     *
     * <p>This method shows how the order of operations in an update expression
     * affects the result of the update.
     *
     * @param dynamoDbClient The DynamoDB client
     * @param tableName The name of the DynamoDB table
     * @param key The key of the item to update
     * @return Map containing the results of different update orders
     * @throws DynamoDbException if an error occurs during the operation
     */
    public static Map<String, Object> demonstrateUpdateOrder(
        DynamoDbClient dynamoDbClient, String tableName, Map<String, AttributeValue>
 key) {

        Map<String, Object> results = new HashMap<>();

        try {
            // Initialize the item with a counter
            UpdateItemRequest initRequest = UpdateItemRequest.builder()
                .tableName(tableName)
                .key(key)
                .updateExpression("SET Counter = :zero, OldCounter = :zero")
                .expressionAttributeValues(
                    Map.of(":zero", AttributeValue.builder().n("0").build()))
                .returnValues(ReturnValue.UPDATED_NEW)
                .build();

- For API details, see [UpdateItem](#) in *AWS SDK for Java 2.x API Reference*.

Use API Gateway to invoke a Lambda function

The following code example shows how to create an AWS Lambda function invoked by Amazon API Gateway.

SDK for Java 2.x

Shows how to create an AWS Lambda function by using the Lambda Java runtime API. This example invokes different AWS services to perform a specific use case. This example

demonstrates how to create a Lambda function invoked by Amazon API Gateway that scans an Amazon DynamoDB table for work anniversaries and uses Amazon Simple Notification Service (Amazon SNS) to send a text message to your employees that congratulates them at their one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon SNS

Use Step Functions to invoke Lambda functions

The following code example shows how to create an AWS Step Functions state machine that invokes AWS Lambda functions in sequence.

SDK for Java 2.x

Shows how to create an AWS serverless workflow by using AWS Step Functions and the AWS SDK for Java 2.x. Each workflow step is implemented using an AWS Lambda function.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
- Lambda
- Amazon SES
- Step Functions

Use atomic counter operations

The following code example shows how to use atomic counter operations in DynamoDB.

- Increment counters atomically using ADD and SET operations.
- Safely increment counters that might not exist.
- Implement optimistic locking for counter operations.

SDK for Java 2.x

Demonstrate atomic counter operations using AWS SDK for Java 2.x.

  - UpdateItem

Use expression attribute names

The following code example shows how to use expression attribute names in DynamoDB.

- Work with reserved words in DynamoDB expressions.
- Use expression attribute name placeholders.
- Handle special characters in attribute names.

SDK for Java 2.x

Demonstrate expression attribute names using AWS SDK for Java 2.x.

Use scheduled events to invoke a Lambda function

The following code example shows how to create an AWS Lambda function invoked by an Amazon EventBridge scheduled event.

SDK for Java 2.x

Shows how to create an Amazon EventBridge scheduled event that invokes an AWS Lambda function. Configure EventBridge to use a cron expression to schedule when the Lambda function is invoked. In this example, you create a Lambda function by using the Lambda Java runtime API. This example invokes different AWS services to perform a specific use case. This example demonstrates how to create an app that sends a mobile text message to your employees that congratulates them at the one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- CloudWatch Logs

- DynamoDB
- EventBridge
- Lambda
- Amazon SNS

Serverless examples

Invoke a Lambda function from a DynamoDB trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from a DynamoDB stream. The function retrieves the DynamoDB payload and logs the record contents.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming a DynamoDB event with Lambda using Java.

```
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.DynamodbEvent;
import
 com.amazonaws.services.lambda.runtime.events.DynamodbEvent.DynamodbStreamRecord;
import com.google.gson.Gson;
import com.google.gson.GsonBuilder;

public class example implements RequestHandler<DynamodbEvent, Void> {

    private static final Gson GSON = new GsonBuilder().setPrettyPrinting().create();

    @Override
    public Void handleRequest(DynamodbEvent event, Context context) {
        System.out.println(GSON.toJson(event));
        event.getRecords().forEach(this::logDynamoDBRecord);
```

```
        return null;
    }

    private void logDynamoDBRecord(DynamodbStreamRecord record) {
        System.out.println(record.getEventID());
        System.out.println(record.getEventName());
        System.out.println("DynamoDB Record: " + GSON.toJson(record.getDynamodb()));
    }
}
```

Reporting batch item failures for Lambda functions with a DynamoDB trigger

The following code example shows how to implement partial batch response for Lambda functions that receive events from a DynamoDB stream. The function reports the batch item failures in the response, signaling to Lambda to retry those messages later.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Reporting DynamoDB batch item failures with Lambda using Java.

StreamsEventResponse.BatchItemFailure(curRecordSequenceNumber));
                return new StreamsEventResponse(batchItemFailures);
            }
        }

       return new StreamsEventResponse();
    }
}
```

AWS community contributions

Build and test a serverless application

The following code example shows how to build and test a serverless application using API Gateway with Lambda and DynamoDB

SDK for Java 2.x

Shows how to build and test a serverless application that consists of an API Gateway with Lambda and DynamoDB using the Java SDK.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- DynamoDB
- Lambda

Amazon EC2 examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon EC2.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon EC2

The following code examples show how to get started using Amazon EC2.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
/**
```

```
    * Asynchronously describes the security groups for the specified group ID.
    *
    * @param groupName the name of the security group to describe
    * @return a {@link CompletableFuture} that represents the asynchronous
operation
    *         of describing the security groups. The future will complete with a
    *         {@link DescribeSecurityGroupsResponse} object that contains the
    *         security group information.
    */
   public CompletableFuture<String> describeSecurityGroupArnByNameAsync(String
groupName) {
       DescribeSecurityGroupsRequest request =
DescribeSecurityGroupsRequest.builder()
           .groupNames(groupName)
           .build();

       DescribeSecurityGroupsPublisher paginator =
getAsyncClient().describeSecurityGroupsPaginator(request);
       AtomicReference<String> groupIdRef = new AtomicReference<>();
       return paginator.subscribe(response -> {
           response.securityGroups().stream()
               .filter(securityGroup ->
securityGroup.groupName().equals(groupName))
               .findFirst()
               .ifPresent(securityGroup ->
groupIdRef.set(securityGroup.groupId()));
       }).thenApply(v -> {
           String groupId = groupIdRef.get();
           if (groupId == null) {
               throw new RuntimeException("No security group found with the name: "
+ groupName);
           }
           return groupId;
       }).exceptionally(ex -> {
           logger.info("Failed to describe security group: " + ex.getMessage());
           throw new RuntimeException("Failed to describe security group", ex);
       });
   }
```

- For API details, see DescribeSecurityGroups in *AWS SDK for Java 2.x API Reference*.

Basics

Learn the basics

The following code example shows how to:

- Create a key pair and security group.
- Select an Amazon Machine Image (AMI) and compatible instance type, then create an instance.
- Stop and restart the instance.
- Associate an Elastic IP address with your instance.
- Connect to your instance with SSH, then clean up resources.

SDK for Java 2.x

import java.util.concurrent.CompletionException;

/**
 * Before running this Java (v2) code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This Java example performs the following tasks:
 *
 * 1. Creates an RSA key pair and saves the private key data as a .pem file.
 * 2. Lists key pairs.
 * 3. Creates a security group for the default VPC.
 * 4. Displays security group information.
 * 5. Gets a list of Amazon Linux 2 AMIs and selects one.
 * 6. Gets additional information about the image.
 * 7. Gets a list of instance types that are compatible with the selected AMI's
 * architecture.
 * 8. Creates an instance with the key pair, security group, AMI, and an
 * instance type.
 * 9. Displays information about the instance.
 * 10. Stops the instance and waits for it to stop.
 * 11. Starts the instance and waits for it to start.
 * 12. Allocates an Elastic IP address and associates it with the instance.
 * 13. Displays SSH connection info for the instance.
 * 14. Disassociates and deletes the Elastic IP address.
 * 15. Terminates the instance and waits for it to terminate.
 * 16. Deletes the security group.
 * 17. Deletes the key pair.
 */

            Amazon Elastic Compute Cloud (EC2) is a web service that provides
 secure, resizable compute
            capacity in the cloud. It allows developers and organizations to easily
 launch and manage
            virtual server instances, known as EC2 instances, to run their
 applications.

            EC2 provides a wide range of instance types, each with different
 compute, memory,
            and storage capabilities, to meet the diverse needs of various
 workloads. Developers
            can choose the appropriate instance type based on their application's
 requirements,
            such as high-performance computing, memory-intensive tasks, or GPU-
accelerated workloads.

            The `Ec2AsyncClient` interface in the AWS SDK for Java 2.x provides a
 set of methods to
            programmatically interact with the Amazon EC2 service. This allows
 developers to
            automate the provisioning, management, and monitoring of EC2 instances
 as part of their
```

```
            application deployment pipelines. With EC2, teams can focus on building
and deploying
            their applications without having to worry about the underlying
infrastructure
            required to host and manage physical servers.

            This scenario walks you through how to perform key operations for this
service.
            Let's get started...
            """);

        waitForInputToContinue(scanner);

throwable.getMessage(), throwable);
       });
   }
```

- For API details, see TerminateInstances in *AWS SDK for Java 2.x API Reference*.

Scenarios

Build and manage a resilient service

The following code example shows how to create a load-balanced web service that returns book, movie, and song recommendations. The example shows how the service responds to failures, and how to restructure the service for more resilience when failures occur.

- Use an Amazon EC2 Auto Scaling group to create Amazon Elastic Compute Cloud (Amazon EC2) instances based on a launch template and to keep the number of instances in a specified range.
- Handle and distribute HTTP requests with Elastic Load Balancing.
- Monitor the health of instances in an Auto Scaling group and forward requests only to healthy instances.
- Run a Python web server on each EC2 instance to handle HTTP requests. The web server responds with recommendations and health checks.
- Simulate a recommendation service with an Amazon DynamoDB table.
- Control web server response to requests and health checks by updating AWS Systems Manager parameters.

Amazon ECR examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon ECR.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon ECR

The following code examples show how to get started using Amazon ECR.

SDK for Java 2.x

> **Note**
>

Topics

- Basics
- Actions

Basics

Learn the basics

The following code example shows how to:

- Create an Amazon ECR repository.
- Set repository policies.
- Retrieve repository URIs.
- Get Amazon ECR authorization tokens.
- Set lifecycle policies for Amazon ECR repositories.
- Push a Docker image to an Amazon ECR repository.
- Verify the existence of an image in an Amazon ECR repository.
- List Amazon ECR repositories for your account and get details about them.
- Delete Amazon ECR repositories.

Run an interactive scenario demonstrating Amazon ECR features.

```
import software.amazon.awssdk.services.ecr.model.EcrException;
import software.amazon.awssdk.services.ecr.model.RepositoryPolicyNotFoundException;

import java.util.Scanner;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This Java code example requires an IAM Role that has permissions to interact with
 the Amazon ECR service.
 *
 * To create an IAM role, see:
 *
 * https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_create.html
 *
 * This Java scenario example requires a local docker image named echo-text. Without
 a local image,
 * this Java program will not successfully run. For more information including how
 to create the local
 * image, see:
 *
 * /scenarios/basics/ecr/README
 *
 */
public class ECRScenario {
    public static final String DASHES = new String(new char[80]).replace("\0", "-");
    public static void main(String[] args) {
        final String usage = """
```

```
            Usage: <iamRoleARN> <accountId>

            Where:
               iamRoleARN - The IAM role ARN that has the necessary permissions to
access and manage the Amazon ECR repository.
               accountId - Your AWS account number.
            """;

        if (args.length != 2) {
            System.out.println(usage);
            return;
        }

        ECRActions ecrActions = new ECRActions();
        String iamRole = args[0];
        String accountId = args[1];
        String localImageName;

        Scanner scanner = new Scanner(System.in);
        System.out.println("""
             The Amazon Elastic Container Registry (ECR) is a fully-managed Docker
container registry
             service provided by AWS. It allows developers and organizations to
securely
             store, manage, and deploy Docker container images.
             ECR provides a simple and scalable way to manage container images
throughout their lifecycle,
             from building and testing to production deployment.\s

             The `EcrAsyncClient` interface in the AWS SDK for Java 2.x provides a
set of methods to
             programmatically interact with the Amazon ECR service. This allows
developers to
             automate the storage, retrieval, and management of container images as
part of their application
             deployment pipelines. With ECR, teams can focus on building and
deploying their
             applications without having to worry about the underlying
infrastructure required to
             host and manage a container registry.

            This scenario walks you through how to perform key operations for this
service.
            Let's get started...
```

```
            You have two choices:
            1 - Run the entire program.
            2 - Delete an existing Amazon ECR repository named echo-text (created
 from a previous execution of
            this program that did not complete).
            """);

        while (true) {
            String input = scanner.nextLine();
            if (input.trim().equalsIgnoreCase("1")) {
                System.out.println("Continuing with the program...");
                System.out.println("");
                break;
            } else if (input.trim().equalsIgnoreCase("2")) {
                String repoName = "echo-text";
                ecrActions.deleteECRRepository(repoName);
                return;
            } else {
                // Handle invalid input.
                System.out.println("Invalid input. Please try again.");
            }
        }

        waitForInputToContinue(scanner);
        System.out.println(DASHES);

        System.out.println("""
           1. Create an ECR repository.

           The first task is to ensure we have a local Docker image named echo-
text.
           If this image exists, then an Amazon ECR repository is created.

Amazon ECS examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon ECS.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`CreateCluster`

The following code example shows how to use `CreateCluster`.

Elastic Load Balancing - Version 2 examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Elastic Load Balancing - Version 2.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Elastic Load Balancing

The following code examples show how to get started using Elastic Load Balancing.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
public class HelloLoadBalancer {

        public static void main(String[] args) {
                ElasticLoadBalancingV2Client loadBalancingV2Client =
 ElasticLoadBalancingV2Client.builder()
                                .region(Region.US_EAST_1)
                                .build();

                DescribeLoadBalancersResponse loadBalancersResponse =
 loadBalancingV2Client
```

```
                                .describeLoadBalancers(r -> r.pageSize(10));
                List<LoadBalancer> loadBalancerList =
 loadBalancersResponse.loadBalancers();
                for (LoadBalancer lb : loadBalancerList)
                        System.out.println("Load Balancer DNS name = " +
 lb.dnsName());
        }
}
```

- For API details, see DescribeLoadBalancers in *AWS SDK for Java 2.x API Reference*.

`CreateLoadBalancer`

The following code example shows how to use `CreateLoadBalancer`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /*
     * Creates an Elastic Load Balancing load balancer that uses the specified
     * subnets
     * and forwards requests to the specified target group.
     */
    public String createLoadBalancer(List<Subnet> subnetIds, String targetGroupARN,
String lbName, int port,
            String protocol) {
        try {
```

```
            List<String> subnetIdStrings = subnetIds.stream()
                    .map(Subnet::subnetId)
                    .collect(Collectors.toList());

            CreateLoadBalancerRequest balancerRequest =
CreateLoadBalancerRequest.builder()
                    .subnets(subnetIdStrings)
                    .name(lbName)
                    .scheme("internet-facing")
                    .build();

            // Create and wait for the load balancer to become available.
            CreateLoadBalancerResponse lsResponse =
getLoadBalancerClient().createLoadBalancer(balancerRequest);
            String lbARN = lsResponse.loadBalancers().get(0).loadBalancerArn();

            ElasticLoadBalancingV2Waiter loadBalancerWaiter =
getLoadBalancerClient().waiter();
            DescribeLoadBalancersRequest request =
DescribeLoadBalancersRequest.builder()
                    .loadBalancerArns(lbARN)
                    .build();

            System.out.println("Waiting for Load Balancer " + lbName + " to become
available.");
            WaiterResponse<DescribeLoadBalancersResponse> waiterResponse =
loadBalancerWaiter
                    .waitUntilLoadBalancerAvailable(request);
            waiterResponse.matched().response().ifPresent(System.out::println);
            System.out.println("Load Balancer " + lbName + " is available.");

            // Get the DNS name (endpoint) of the load balancer.
            String lbDNSName = lsResponse.loadBalancers().get(0).dnsName();
            System.out.println("*** Load Balancer DNS Name: " + lbDNSName);

            // Create a listener for the load balance.
            Action action = Action.builder()
                    .targetGroupArn(targetGroupARN)
                    .type("forward")
                    .build();

            CreateListenerRequest listenerRequest = CreateListenerRequest.builder()

.loadBalancerArn(lsResponse.loadBalancers().get(0).loadBalancerArn())
```

```
                    .defaultActions(action)
                    .port(port)
                    .protocol(protocol)
                    .build();

            getLoadBalancerClient().createListener(listenerRequest);
            System.out.println("Created listener to forward traffic from load
balancer " + lbName + " to target group "
                    + targetGroupARN);

            // Return the load balancer DNS name.
            return lbDNSName;

        } catch (ElasticLoadBalancingV2Exception e) {
            e.printStackTrace();
        }
        return "";
    }
```

`CreateTargetGroup`

The following code example shows how to use `CreateTargetGroup`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /*
     * Creates an Elastic Load Balancing target group. The target group specifies
     * how
     * the load balancer forward requests to instances in the group and how instance
     * health is checked.
     */
    public String createTargetGroup(String protocol, int port, String vpcId, String
targetGroupName) {
```

```
        CreateTargetGroupRequest targetGroupRequest =
CreateTargetGroupRequest.builder()
                .healthCheckPath("/healthcheck")
                .healthCheckTimeoutSeconds(5)
                .port(port)
                .vpcId(vpcId)
                .name(targetGroupName)
                .protocol(protocol)
                .build();

        CreateTargetGroupResponse targetGroupResponse =
getLoadBalancerClient().createTargetGroup(targetGroupRequest);
        String targetGroupArn =
targetGroupResponse.targetGroups().get(0).targetGroupArn();
        String targetGroup =
targetGroupResponse.targetGroups().get(0).targetGroupName();
        System.out.println("The " + targetGroup + " was created with ARN" +
targetGroupArn);
        return targetGroupArn;
    }
```

- For API details, see CreateTargetGroup in *AWS SDK for Java 2.x API Reference*.

`DeleteLoadBalancer`

The following code example shows how to use `DeleteLoadBalancer`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    // Deletes a load balancer.
    public void deleteLoadBalancer(String lbName) {
        try {
            // Use a waiter to delete the Load Balancer.
            DescribeLoadBalancersResponse res = getLoadBalancerClient()
                    .describeLoadBalancers(describe -> describe.names(lbName));
```

```
            ElasticLoadBalancingV2Waiter loadBalancerWaiter =
getLoadBalancerClient().waiter();
            DescribeLoadBalancersRequest request =
DescribeLoadBalancersRequest.builder()
                    .loadBalancerArns(res.loadBalancers().get(0).loadBalancerArn())
                    .build();

            getLoadBalancerClient().deleteLoadBalancer(
                    builder ->
builder.loadBalancerArn(res.loadBalancers().get(0).loadBalancerArn()));
            WaiterResponse<DescribeLoadBalancersResponse> waiterResponse =
loadBalancerWaiter
                    .waitUntilLoadBalancersDeleted(request);
            waiterResponse.matched().response().ifPresent(System.out::println);

        } catch (ElasticLoadBalancingV2Exception e) {
            System.err.println(e.awsErrorDetails().errorMessage());
        }
        System.out.println(lbName + " was deleted.");
    }
```

- For API details, see DeleteLoadBalancer in *AWS SDK for Java 2.x API Reference*.

`DeleteTargetGroup`

The following code example shows how to use `DeleteTargetGroup`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    // Deletes the target group.
    public void deleteTargetGroup(String targetGroupName) {
        try {
            DescribeTargetGroupsResponse res = getLoadBalancerClient()
                    .describeTargetGroups(describe ->
describe.names(targetGroupName));
```

```
            getLoadBalancerClient()
                    .deleteTargetGroup(builder ->
builder.targetGroupArn(res.targetGroups().get(0).targetGroupArn()));
        } catch (ElasticLoadBalancingV2Exception e) {
            System.err.println(e.awsErrorDetails().errorMessage());
        }
        System.out.println(targetGroupName + " was deleted.");
    }
```

- For API details, see DeleteTargetGroup in *AWS SDK for Java 2.x API Reference*.

`DescribeTargetHealth`

The following code example shows how to use `DescribeTargetHealth`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    // Checks the health of the instances in the target group.
    public List<TargetHealthDescription> checkTargetHealth(String targetGroupName) {
        DescribeTargetGroupsRequest targetGroupsRequest =
DescribeTargetGroupsRequest.builder()
                .names(targetGroupName)
                .build();

        DescribeTargetGroupsResponse tgResponse =
getLoadBalancerClient().describeTargetGroups(targetGroupsRequest);

        DescribeTargetHealthRequest healthRequest =
DescribeTargetHealthRequest.builder()
                .targetGroupArn(tgResponse.targetGroups().get(0).targetGroupArn())
                .build();

        DescribeTargetHealthResponse healthResponse =
getLoadBalancerClient().describeTargetHealth(healthRequest);
        return healthResponse.targetHealthDescriptions();
```

```
    }
```

- For API details, see DescribeTargetHealth in *AWS SDK for Java 2.x API Reference*.

Scenarios

Build and manage a resilient service

The following code example shows how to create a load-balanced web service that returns book, movie, and song recommendations. The example shows how the service responds to failures, and how to restructure the service for more resilience when failures occur.

- Use an Amazon EC2 Auto Scaling group to create Amazon Elastic Compute Cloud (Amazon EC2) instances based on a launch template and to keep the number of instances in a specified range.
- Handle and distribute HTTP requests with Elastic Load Balancing.
- Monitor the health of instances in an Auto Scaling group and forward requests only to healthy instances.
- Run a Python web server on each EC2 instance to handle HTTP requests. The web server responds with recommendations and health checks.
- Simulate a recommendation service with an Amazon DynamoDB table.
- Control web server response to requests and health checks by updating AWS Systems Manager parameters.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run the interactive scenario at a command prompt.

```
public class Main {

```
   private static void deleteResources(LoadBalancer loadBalancer, AutoScaler
autoScaler, Database database)
           throws IOException, InterruptedException {
       loadBalancer.deleteLoadBalancer(lbName);
       System.out.println("*** Wait 30 secs for resource to be deleted");
       TimeUnit.SECONDS.sleep(30);
       loadBalancer.deleteTargetGroup(targetGroupName);
       autoScaler.deleteAutoScaleGroup(autoScalingGroupName);
       autoScaler.deleteRolesPolicies(policyName, roleName, profileName);
       autoScaler.deleteTemplate(templateName);
       database.deleteTable(tableName);
   }

   private static void deploy(LoadBalancer loadBalancer) throws
InterruptedException, IOException {
       Scanner in = new Scanner(System.in);
       System.out.println(
               """
                       For this demo, we'll use the AWS SDK for Java (v2) to create
several AWS resources
                       to set up a load-balanced web service endpoint and explore
some ways to make it resilient
                       against various kinds of failures.

                       Some of the resources create by this demo are:
                       \t* A DynamoDB table that the web service depends on to
provide book, movie, and song recommendations.
                       \t* An EC2 launch template that defines EC2 instances that
each contain a Python web server.
                       \t* An EC2 Auto Scaling group that manages EC2 instances
across several Availability Zones.
                       \t* An Elastic Load Balancing (ELB) load balancer that
targets the Auto Scaling group to distribute requests.
                       """);

       System.out.println("Press Enter when you're ready.");
       in.nextLine();
       System.out.println(DASHES);

       System.out.println("Creating and populating a DynamoDB table named " +
tableName);
       Database database = new Database();
       database.createTable(tableName, fileName);
```

```
        System.out.println(DASHES);

        System.out.println(DASHES);
        System.out.println("""
                Creating an EC2 launch template that runs '{startup_script}' when an
instance starts.
                This script starts a Python web server defined in the `server.py`
script. The web server
                listens to HTTP requests on port 80 and responds to requests to '/'
and to '/healthcheck'.
                For demo purposes, this server is run as the root user. In
production, the best practice is to
                run a web server, such as Apache, with least-privileged credentials.

                The template also defines an IAM policy that each instance uses to
assume a role that grants
                permissions to access the DynamoDB recommendation table and Systems
Manager parameters
                that control the flow of the demo.
                """);

        LaunchTemplateCreator templateCreator = new LaunchTemplateCreator();
        templateCreator.createTemplate(policyFile, policyName, profileName,

MediaStore examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with MediaStore.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

AWS Entity Resolution examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with AWS Entity Resolution.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello AWS Entity Resolution

The following code examples show how to get started using AWS Entity Resolution.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class HelloEntityResoultion {

    private static final Logger logger =
 LoggerFactory.getLogger(HelloEntityResoultion.class);

    private static EntityResolutionAsyncClient entityResolutionAsyncClient;
    public static void main(String[] args) {
        listMatchingWorkflows();
    }

    public static EntityResolutionAsyncClient getResolutionAsyncClient() {
        if (entityResolutionAsyncClient == null) {
            /*
            The `NettyNioAsyncHttpClient` class is part of the AWS SDK for Java,
 version 2,
```

```
            and it is designed to provide a high-performance, asynchronous HTTP
client for interacting with AWS services.
             It uses the Netty framework to handle the underlying network
communication and the Java NIO API to
             provide a non-blocking, event-driven approach to HTTP requests and
responses.
             */

            SdkAsyncHttpClient httpClient = NettyNioAsyncHttpClient.builder()
                .maxConcurrency(50)  // Adjust as needed.
                .connectionTimeout(Duration.ofSeconds(60))  // Set the connection
timeout.
                .readTimeout(Duration.ofSeconds(60))  // Set the read timeout.
                .writeTimeout(Duration.ofSeconds(60))  // Set the write timeout.
                .build();

            ClientOverrideConfiguration overrideConfig =
ClientOverrideConfiguration.builder()
                .apiCallTimeout(Duration.ofMinutes(2))  // Set the overall API call
timeout.
                .apiCallAttemptTimeout(Duration.ofSeconds(90))  // Set the
individual call attempt timeout.
                .retryStrategy(RetryMode.STANDARD)
                .build();

            entityResolutionAsyncClient = EntityResolutionAsyncClient.builder()
                .httpClient(httpClient)
                .overrideConfiguration(overrideConfig)
                .build();
        }
        return entityResolutionAsyncClient;
    }

    /**
     * Lists all matching workflows using an asynchronous paginator.
     * <p>
     * This method requests a paginated list of matching workflows from the
     * AWS Entity Resolution service and logs the names of the retrieved workflows.
     * It uses an asynchronous approach with a paginator and waits for the operation
     * to complete using {@code CompletableFuture#join()}.
     * </p>
     */
    public static void listMatchingWorkflows() {
```

```
        ListMatchingWorkflowsRequest request =
 ListMatchingWorkflowsRequest.builder().build();

        ListMatchingWorkflowsPublisher paginator =
            getResolutionAsyncClient().listMatchingWorkflowsPaginator(request);

        // Iterate through the paginated results asynchronously
        CompletableFuture<Void> future = paginator.subscribe(response -> {
            response.workflowSummaries().forEach(workflow ->
                logger.info("Matching Workflow Name: " + workflow.workflowName())
            );
        });

        // Wait for the asynchronous operation to complete
        future.join();
    }
}
```

- For API details, see listMatchingWorkflows in *AWS SDK for Java 2.x API Reference*.

Topics

- Basics
- Actions

Basics

Learn the basics

The following code example shows how to:

- Create Schema Mapping.
- Create an AWS Entity Resolution workflow.
- Start the matching job for the workflow.
- Get details for the matching job.
- Get Schema Mapping.
- List all Schema Mappings.
- Tag the Schema Mapping resource.

- Delete the AWS Entity Resolution Assets.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario demonstrating AWS Entity Resolution features.

```
public class EntityResScenario {
    private static final Logger logger =
 LoggerFactory.getLogger(EntityResScenario.class);
    public static final String DASHES = new String(new char[80]).replace("\0", "-");
    private static final String STACK_NAME = "EntityResolutionCdkStack";
    private static final String ENTITY_RESOLUTION_ROLE_ARN_KEY =
 "EntityResolutionRoleArn";
    private static final String GLUE_DATA_BUCKET_NAME_KEY = "GlueDataBucketName";
    private static final String JSON_GLUE_TABLE_ARN_KEY = "JsonErGlueTableArn";
    private static final String CSV_GLUE_TABLE_ARN_KEY = "CsvErGlueTableArn";
    private static String glueBucketName;
    private static String workflowName = "workflow-" + UUID.randomUUID();

    private static String jsonSchemaMappingName = "jsonschema-" + UUID.randomUUID();
    private static String jsonSchemaMappingArn = null;
    private static String csvSchemaMappingName = "csv-" + UUID.randomUUID();
    private static String roleARN;
    private static String csvGlueTableArn;
    private static String jsonGlueTableArn;
    private static Scanner scanner = new Scanner(System.in);

    private static EntityResActions actions = new EntityResActions();

    public static void main(String[] args) throws InterruptedException {

        logger.info("Welcome to the AWS Entity Resolution Scenario.");
        logger.info("""
            AWS Entity Resolution is a fully-managed machine learning service
 provided by
            Amazon Web Services (AWS) that helps organizations extract, link, and
```

```
            organize information from multiple data sources. It leverages natural
            language processing and deep learning models to identify and resolve
            entities, such as people, places, organizations, and products,
            across structured and unstructured data.

            With Entity Resolution, customers can build robust data integration
            pipelines to combine and reconcile data from multiple systems,
databases,
            and documents. The service can handle ambiguous, incomplete, or
conflicting
            information, and provide a unified view of entities and their
relationships.
            This can be particularly valuable in applications such as customer 360,
            fraud detection, supply chain management, and knowledge management,
where
            accurate entity identification is crucial.

            The `EntityResolutionAsyncClient` interface in the AWS SDK for Java 2.x
            provides a set of methods to programmatically interact with the AWS
Entity
            Resolution service. This allows developers to automate the entity
extraction,
            linking, and deduplication process as part of their data processing
workflows.
            With Entity Resolution, organizations can unlock the value of their
data,
            improve decision-making, and enhance customer experiences by having a
reliable,
            comprehensive view of their key entities.
            """);

        waitForInputToContinue(scanner);
        logger.info(DASHES);

        logger.info(DASHES);
        logger.info("""
            To prepare the AWS resources needed for this scenario application, the
next step uploads
            a CloudFormation template whose resulting stack creates the following
resources:
            - An AWS Glue Data Catalog table
            - An AWS IAM role
            - An AWS S3 bucket
            - An AWS Entity Resolution Schema
```

```
            It can take a couple minutes for the Stack to finish creating the
resources.

                   throw new CompletionException("Failed to tag the resource: " +
exception.getMessage(), exception);
```

```
                }
            });
    }
```

- For API details, see TagEntityResource in *AWS SDK for Java 2.x API Reference*.

OpenSearch Service examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with OpenSearch Service.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello OpenSearch Service

The following code example shows how to get started using OpenSearch Service.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import software.amazon.awssdk.services.opensearch.OpenSearchAsyncClient;
import software.amazon.awssdk.services.opensearch.model.ListVersionsRequest;
import java.util.List;
import java.util.concurrent.CompletableFuture;

/**
 * Before running this Java V2 code example, set up your development
```

```
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class HelloOpenSearch {
    public static void main(String[] args) {
        try {
            CompletableFuture<Void> future = listVersionsAsync();
            future.join();
            System.out.println("Versions listed successfully.");
        } catch (RuntimeException e) {
            System.err.println("Error occurred while listing versions: " +
 e.getMessage());
        }
    }

    private static OpenSearchAsyncClient getAsyncClient() {
        return OpenSearchAsyncClient.builder().build();
    }

    public static CompletableFuture<Void> listVersionsAsync() {
        ListVersionsRequest request = ListVersionsRequest.builder()
            .maxResults(10)
            .build();

        return getAsyncClient().listVersions(request).thenAccept(response -> {
            List<String> versionList = response.versions();
            for (String version : versionList) {
                System.out.println("Version info: " + version);
            }
        }).exceptionally(ex -> {
            // Handle the exception, or propagate it as a RuntimeException
            throw new RuntimeException("Failed to list versions", ex);
        });
    }
}
```

- For API details, see ListVersions in *AWS SDK for Java 2.x API Reference*.

Topics

- Basics
- Actions

Basics

Learn OpenSearch Service core operations

The following code example shows how to:

- Create an OpenSearch Service domain.
- Provides detailed information about a specific OpenSearch Service domain.
- Lists all the OpenSearch Service domains owned by the account.
- Waits until the OpenSearch Service domain's change status reaches a completed state.
- Modifies the configuration of an existing OpenSearch Service domain.
- Add a tag to the OpenSearch Service domain.
- Lists the tags associated with an OpenSearch Service domain.
- Removes tags from an OpenSearch Service domain.
- Deletes the OpenSearch Service domain.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario demonstrating OpenSearch Service features.

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.services.opensearch.model.*;
import java.util.List;
import java.util.Scanner;
import java.util.concurrent.CompletableFuture;

public class OpenSearchScenario {
```

```
    public static final String DASHES = new String(new char[80]).replace("\0", "-");

    private static final Logger logger =
 LoggerFactory.getLogger(OpenSearchScenario.class);

Actions

AddTags

The following code example shows how to use AddTags.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   /**
    * Asynchronously adds tags to an Amazon OpenSearch Service domain.
    * @param domainARN the Amazon Resource Name (ARN) of the Amazon OpenSearch
Service domain to add tags to
    * @return a {@link CompletableFuture} that completes when the tags have been
successfully added to the domain,
    * or throws a {@link RuntimeException} if the operation fails
    */
   public CompletableFuture<AddTagsResponse> addDomainTagsAsync(String domainARN) {
       Tag tag1 = Tag.builder()
           .key("service")
           .value("OpenSearch")
           .build();

       Tag tag2 = Tag.builder()
           .key("instances")
           .value("m3.2xlarge")
           .build();

       List<Tag> tagList = new ArrayList<>();
       tagList.add(tag1);
       tagList.add(tag2);

       AddTagsRequest addTagsRequest = AddTagsRequest.builder()
           .arn(domainARN)
           .tagList(tagList)
           .build();
```

```
        return getAsyncClient().addTags(addTagsRequest)
            .whenComplete((response, exception) -> {
                if (exception != null) {
                    throw new RuntimeException("Failed to add tags to the domain: "
+ domainARN, exception);
                } else {
                    logger.info("Added Tags");
                }
            });
    }
```

EventBridge examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with EventBridge.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello EventBridge

The following code examples show how to get started using EventBridge.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 */
public class HelloEventBridge {
    public static void main(String[] args) {
        Region region = Region.US_WEST_2;
        EventBridgeClient eventBrClient = EventBridgeClient.builder()
                .region(region)
                .build();

        listBuses(eventBrClient);
        eventBrClient.close();
    }

    public static void listBuses(EventBridgeClient eventBrClient) {
        try {
            ListEventBusesRequest busesRequest = ListEventBusesRequest.builder()
                    .limit(10)

Basics

Learn the basics

The following code example shows how to:

- Create a rule and add a target to it.
- Enable and disable rules.
- List and update rules and targets.
- Send events, then clean up resources.

SDK for Java 2.x

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This Java code example performs the following tasks:
 *
 * This Java V2 example performs the following tasks with Amazon EventBridge:
 *
 * 1. Creates an AWS Identity and Access Management (IAM) role to use with
 * Amazon EventBridge.
 * 2. Amazon Simple Storage Service (Amazon S3) bucket with EventBridge events
 * enabled.
 * 3. Creates a rule that triggers when an object is uploaded to Amazon S3.
 * 4. Lists rules on the event bus.
 * 5. Creates a new Amazon Simple Notification Service (Amazon SNS) topic and
 * lets the user subscribe to it.
 * 6. Adds a target to the rule that sends an email to the specified topic.
 * 7. Creates an EventBridge event that sends an email when an Amazon S3 object
 * is created.
 * 8. Lists Targets.
 * 9. Lists the rules for the same target.
 * 10. Triggers the rule by uploading a file to the Amazon S3 bucket.
 * 11. Disables a specific rule.
 * 12. Checks and print the state of the rule.
 * 13. Adds a transform to the rule to change the text of the email.
 * 14. Enables a specific rule.
 * 15. Triggers the updated rule by uploading a file to the Amazon S3 bucket.
 * 16. Updates the rule to be a custom rule pattern.
 * 17. Sending an event to trigger the rule.
 * 18. Cleans up resources.

Actions

`DeleteRule`

The following code example shows how to use `DeleteRule`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   public static void deleteRuleByName(EventBridgeClient eventBrClient, String
ruleName) {
       DeleteRuleRequest ruleRequest = DeleteRuleRequest.builder()
               .name(ruleName)
               .build();

       eventBrClient.deleteRule(ruleRequest);
       System.out.println("Successfully deleted the rule");
```

```
    }
```

- For API details, see DeleteRule in *AWS SDK for Java 2.x API Reference*.

`DescribeRule`

The following code example shows how to use `DescribeRule`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   public static void checkRule(EventBridgeClient eventBrClient, String
eventRuleName) {
       try {
           DescribeRuleRequest ruleRequest = DescribeRuleRequest.builder()
                   .name(eventRuleName)
                   .build();

           DescribeRuleResponse response = eventBrClient.describeRule(ruleRequest);
           System.out.println("The state of the rule is " +
response.stateAsString());

       } catch (EventBridgeException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see DescribeRule in *AWS SDK for Java 2.x API Reference*.

`DisableRule`

The following code example shows how to use `DisableRule`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Disable a rule by using its rule name.

```
   public static void changeRuleState(EventBridgeClient eventBrClient, String
eventRuleName, Boolean isEnabled) {
       try {
           if (!isEnabled) {
               System.out.println("Disabling the rule: " + eventRuleName);
               DisableRuleRequest ruleRequest = DisableRuleRequest.builder()
                       .name(eventRuleName)
                       .build();

               eventBrClient.disableRule(ruleRequest);
           } else {
               System.out.println("Enabling the rule: " + eventRuleName);
               EnableRuleRequest ruleRequest = EnableRuleRequest.builder()
                       .name(eventRuleName)
                       .build();
               eventBrClient.enableRule(ruleRequest);
           }

       } catch (EventBridgeException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see DisableRule in *AWS SDK for Java 2.x API Reference*.

`EnableRule`

The following code example shows how to use `EnableRule`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Enable a rule by using its rule name.

```
   public static void changeRuleState(EventBridgeClient eventBrClient, String
eventRuleName, Boolean isEnabled) {
       try {
           if (!isEnabled) {
               System.out.println("Disabling the rule: " + eventRuleName);
               DisableRuleRequest ruleRequest = DisableRuleRequest.builder()
                       .name(eventRuleName)
                       .build();

               eventBrClient.disableRule(ruleRequest);
           } else {
               System.out.println("Enabling the rule: " + eventRuleName);
               EnableRuleRequest ruleRequest = EnableRuleRequest.builder()
                       .name(eventRuleName)
                       .build();
               eventBrClient.enableRule(ruleRequest);
           }

       } catch (EventBridgeException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see EnableRule in *AWS SDK for Java 2.x API Reference*.

`ListRuleNamesByTarget`

The following code example shows how to use `ListRuleNamesByTarget`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

List all of the rule names by using the target.

```
   public static void listTargetRules(EventBridgeClient eventBrClient, String
topicArn) {
       ListRuleNamesByTargetRequest ruleNamesByTargetRequest =
ListRuleNamesByTargetRequest.builder()
               .targetArn(topicArn)
               .build();

       ListRuleNamesByTargetResponse response =
eventBrClient.listRuleNamesByTarget(ruleNamesByTargetRequest);
       List<String> rules = response.ruleNames();
       for (String rule : rules) {
           System.out.println("The rule name is " + rule);
       }
   }
```

- For API details, see ListRuleNamesByTarget in *AWS SDK for Java 2.x API Reference*.

`ListRules`

The following code example shows how to use `ListRules`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Enable a rule by using its rule name.

```
    public static void listRules(EventBridgeClient eventBrClient) {
        try {
            ListRulesRequest rulesRequest = ListRulesRequest.builder()
                    .eventBusName("default")
                    .limit(10)
                    .build();

            ListRulesResponse response = eventBrClient.listRules(rulesRequest);
            List<Rule> rules = response.rules();
            for (Rule rule : rules) {
                System.out.println("The rule name is : " + rule.name());
                System.out.println("The rule description is : " +
rule.description());
                System.out.println("The rule state is : " + rule.stateAsString());
            }

        } catch (EventBridgeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see ListRules in *AWS SDK for Java 2.x API Reference*.

`ListTargetsByRule`

The following code example shows how to use `ListTargetsByRule`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

List all of the targets for a rule by using the rule name.

```
    public static void listTargets(EventBridgeClient eventBrClient, String ruleName)
{
```

```
        ListTargetsByRuleRequest ruleRequest = ListTargetsByRuleRequest.builder()
                .rule(ruleName)
                .build();

        ListTargetsByRuleResponse res =
eventBrClient.listTargetsByRule(ruleRequest);
        List<Target> targetsList = res.targets();
        for (Target target: targetsList) {
            System.out.println("Target ARN: "+target.arn());
        }
    }
```

- For API details, see ListTargetsByRule in *AWS SDK for Java 2.x API Reference*.

`PutEvents`

The following code example shows how to use `PutEvents`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    public static void triggerCustomRule(EventBridgeClient eventBrClient, String
email) {
        String json = "{" +
                "\"UserEmail\": \"" + email + "\"," +
                "\"Message\": \"This event was generated by example code.\"," +
                "\"UtcTime\": \"Now.\"" +
                "}";

        PutEventsRequestEntry entry = PutEventsRequestEntry.builder()
                .source("ExampleSource")
                .detail(json)
                .detailType("ExampleType")
                .build();
```

```
        PutEventsRequest eventsRequest = PutEventsRequest.builder()
                .entries(entry)
                .build();

        eventBrClient.putEvents(eventsRequest);
    }
```

- For API details, see PutEvents in *AWS SDK for Java 2.x API Reference*.

`PutRule`

The following code example shows how to use `PutRule`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Create a scheduled rule.

```
   public static void createEBRule(EventBridgeClient eventBrClient, String
ruleName, String cronExpression) {
       try {
           PutRuleRequest ruleRequest = PutRuleRequest.builder()
                   .name(ruleName)
                   .eventBusName("default")
                   .scheduleExpression(cronExpression)
                   .state("ENABLED")
                   .description("A test rule that runs on a schedule created by the
Java API")
                   .build();

           PutRuleResponse ruleResponse = eventBrClient.putRule(ruleRequest);
           System.out.println("The ARN of the new rule is " +
ruleResponse.ruleArn());

       } catch (EventBridgeException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
```

```
            System.exit(1);
        }
    }
```

Create a rule that triggers when an object is added to an Amazon Simple Storage Service bucket.

```
    // Create a new event rule that triggers when an Amazon S3 object is created in
    // a bucket.
    public static void addEventRule(EventBridgeClient eventBrClient, String roleArn,
String bucketName,
            String eventRuleName) {
        String pattern = "{\n" +
                "  \"source\": [\"aws.s3\"],\n" +
                "  \"detail-type\": [\"Object Created\"],\n" +
                "  \"detail\": {\n" +
                "    \"bucket\": {\n" +
                "      \"name\": [\"" + bucketName + "\"]\n" +
                "    }\n" +
                "  }\n" +
                "}";

        try {
            PutRuleRequest ruleRequest = PutRuleRequest.builder()
                    .description("Created by using the AWS SDK for Java v2")
                    .name(eventRuleName)
                    .eventPattern(pattern)
                    .roleArn(roleArn)
                    .build();

            PutRuleResponse ruleResponse = eventBrClient.putRule(ruleRequest);
            System.out.println("The ARN of the new rule is " +
ruleResponse.ruleArn());

        } catch (EventBridgeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see PutRule in *AWS SDK for Java 2.x API Reference*.

`PutTargets`

The following code example shows how to use `PutTargets`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Add an Amazon SNS topic as a target for a rule.

```
   // Add a rule which triggers an SNS target when a file is uploaded to an S3
   // bucket.
   public static void addSnsEventRule(EventBridgeClient eventBrClient, String
ruleName, String topicArn,
           String topicName, String eventRuleName, String bucketName) {
       String targetID = java.util.UUID.randomUUID().toString();
       Target myTarget = Target.builder()
               .id(targetID)
               .arn(topicArn)
               .build();

       List<Target> targets = new ArrayList<>();
       targets.add(myTarget);
       PutTargetsRequest request = PutTargetsRequest.builder()
               .eventBusName(null)
               .targets(targets)
               .rule(ruleName)
               .build();

       eventBrClient.putTargets(request);
       System.out.println("Added event rule " + eventRuleName + " with Amazon SNS
target " + topicName + " for bucket "
               + bucketName + ".");
   }
```

Add an input transformer to a target for a rule.

```
   public static void updateCustomRuleTargetWithTransform(EventBridgeClient
eventBrClient, String topicArn,
           String ruleName) {
       String targetId = java.util.UUID.randomUUID().toString();
       InputTransformer inputTransformer = InputTransformer.builder()
               .inputTemplate("\"Notification: sample event was received.\"")
               .build();

       Target target = Target.builder()
               .id(targetId)
               .arn(topicArn)
               .inputTransformer(inputTransformer)
               .build();

       try {
           PutTargetsRequest targetsRequest = PutTargetsRequest.builder()
                   .rule(ruleName)
                   .targets(target)
                   .eventBusName(null)
                   .build();

           eventBrClient.putTargets(targetsRequest);
       } catch (EventBridgeException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see PutTargets in *AWS SDK for Java 2.x API Reference*.

`RemoveTargets`

The following code example shows how to use `RemoveTargets`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Remove all of the targets for a rule by using the rule name.

```
   public static void deleteTargetsFromRule(EventBridgeClient eventBrClient, String
eventRuleName) {
       // First, get all targets that will be deleted.
       ListTargetsByRuleRequest request = ListTargetsByRuleRequest.builder()
               .rule(eventRuleName)
               .build();

       ListTargetsByRuleResponse response =
eventBrClient.listTargetsByRule(request);
       List<Target> allTargets = response.targets();

       // Get all targets and delete them.
       for (Target myTarget : allTargets) {
           RemoveTargetsRequest removeTargetsRequest =
RemoveTargetsRequest.builder()
                   .rule(eventRuleName)
                   .ids(myTarget.id())
                   .build();

           eventBrClient.removeTargets(removeTargetsRequest);
           System.out.println("Successfully removed the target");
       }
   }
```

- For API details, see RemoveTargets in *AWS SDK for Java 2.x API Reference*.

Scenarios

Send event notifications to EventBridge

The following code example shows how to enable a bucket to send S3 event notifications to EventBridge and route notifications to an Amazon SNS topic and Amazon SQS queue.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   /** This method configures a bucket to send events to AWS EventBridge and
creates a rule
    * to route the S3 object created events to a topic and a queue.
    *
    * @param bucketName Name of existing bucket
    * @param topicArn ARN of existing topic to receive S3 event notifications
    * @param queueArn ARN of existing queue to receive S3 event notifications
    *
    *  An AWS CloudFormation stack sets up the bucket, queue, topic before the
method runs.
    */
   public static String setBucketNotificationToEventBridge(String bucketName,
String topicArn, String queueArn) {
       try {
           // Enable bucket to emit S3 Event notifications to EventBridge.
           s3Client.putBucketNotificationConfiguration(b -> b
                   .bucket(bucketName)
                   .notificationConfiguration(b1 -> b1
                           .eventBridgeConfiguration(
                                   SdkBuilder::build)
                   ).build()).join();

           // Create an EventBridge rule to route Object Created notifications.
           PutRuleRequest putRuleRequest = PutRuleRequest.builder()
                   .name(RULE_NAME)
                   .eventPattern("""
                           {
                             "source": ["aws.s3"],
                             "detail-type": ["Object Created"],
                             "detail": {
                               "bucket": {
                                 "name": ["%s"]
                               }
                             }
```

```
                            }
                            """.formatted(bucketName))
                    .build();

            // Add the rule to the default event bus.
            PutRuleResponse putRuleResponse =
eventBridgeClient.putRule(putRuleRequest)
                    .whenComplete((r, t) -> {
                        if (t != null) {
                            logger.error("Error creating event bus rule: " +
t.getMessage(), t);
                            throw new RuntimeException(t.getCause().getMessage(),
t);
                        }
                        logger.info("Event bus rule creation request sent
successfully. ARN is: {}", r.ruleArn());
                    }).join();

            // Add the existing SNS topic and SQS queue as targets to the rule.
            eventBridgeClient.putTargets(b -> b
                    .eventBusName("default")
                    .rule(RULE_NAME)
                    .targets(List.of (
                            Target.builder()
                                    .arn(queueArn)
                                    .id("Queue")
                                    .build(),
                            Target.builder()
                                    .arn(topicArn)
                                    .id("Topic")
                                    .build())
                            )
                    ).join();
            return putRuleResponse.ruleArn();
        } catch (S3Exception e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
        return null;
    }
```

Use scheduled events to invoke a Lambda function

The following code example shows how to create an AWS Lambda function invoked by an Amazon EventBridge scheduled event.

SDK for Java 2.x

Shows how to create an Amazon EventBridge scheduled event that invokes an AWS Lambda function. Configure EventBridge to use a cron expression to schedule when the Lambda function is invoked. In this example, you create a Lambda function by using the Lambda Java runtime API. This example invokes different AWS services to perform a specific use case. This example demonstrates how to create an app that sends a mobile text message to your employees that congratulates them at the one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- CloudWatch Logs
- DynamoDB
- EventBridge
- Lambda
- Amazon SNS

EventBridge Scheduler examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with EventBridge Scheduler.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello EventBridge Scheduler

The following code examples show how to get started using EventBridge Scheduler.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import software.amazon.awssdk.services.scheduler.SchedulerAsyncClient;
import software.amazon.awssdk.services.scheduler.model.ListSchedulesRequest;
import software.amazon.awssdk.services.scheduler.model.ScheduleSummary;
import software.amazon.awssdk.services.scheduler.paginators.ListSchedulesPublisher;
import java.util.ArrayList;
import java.util.List;
import java.util.concurrent.CompletableFuture;

public class HelloScheduler {

    public static void main(String [] args) {
        listSchedulesAsync();
    }

    /**
     * Lists all the schedules available.
     * <p>
     * This method uses the {@link SchedulerAsyncClient} to make an asynchronous
 request to
     * list all the schedules available. The method uses the {@link
 ListSchedulesPublisher}
     * to fetch the schedules in a paginated manner, and then processes the
 responses
```

```
     * asynchronously.
     */
    public static void listSchedulesAsync() {
        SchedulerAsyncClient schedulerAsyncClient = SchedulerAsyncClient.create();

        // Build the request to list schedules
        ListSchedulesRequest listSchedulesRequest =
 ListSchedulesRequest.builder().build();

        // Use the paginator to fetch all schedules asynchronously.
        ListSchedulesPublisher paginator =
 schedulerAsyncClient.listSchedulesPaginator(listSchedulesRequest);
        List<ScheduleSummary> results = new ArrayList<>();

        // Subscribe to the paginator to process the response asynchronously
        CompletableFuture<Void> future = paginator.subscribe(response -> {
            response.schedules().forEach(schedule -> {
                results.add(schedule);
                System.out.printf("Schedule: %s%n", schedule.name());
            });
        });

        // Wait for the asynchronous operation to complete.
        future.join();

        // After all schedules are fetched, print the total count.
        System.out.printf("Total of %d schedule(s) available.%n", results.size());
    }
}
```

Actions

`CreateSchedule`

The following code example shows how to use `CreateSchedule`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   /**
    * Creates a new schedule for a target task.
    *
    * @param name                  the name of the schedule
    * @param scheduleExpression    The schedule expression that defines when the
schedule should run.
    * @param scheduleGroupName     the name of the schedule group to which the
schedule belongs
    * @param targetArn             the Amazon Resource Name (ARN) of the target
task
    * @param roleArn               the ARN of the IAM role to be used for the
schedule
    * @param input                 the input data for the target task
    * @param deleteAfterCompletion whether to delete the schedule after it's
executed
    * @param useFlexibleTimeWindow whether to use a flexible time window for the
schedule execution
    * @return true if the schedule was successfully created, false otherwise
    */
   public CompletableFuture<Boolean> createScheduleAsync(
       String name,
       String scheduleExpression,
       String scheduleGroupName,
       String targetArn,
       String roleArn,
       String input,
       boolean deleteAfterCompletion,
```

```
        boolean useFlexibleTimeWindow) {

        int hoursToRun = 1;
        int flexibleTimeWindowMinutes = 10;

        Target target = Target.builder()
            .arn(targetArn)
            .roleArn(roleArn)
            .input(input)
            .build();

        FlexibleTimeWindow flexibleTimeWindow = FlexibleTimeWindow.builder()
            .mode(useFlexibleTimeWindow
                ? FlexibleTimeWindowMode.FLEXIBLE
                : FlexibleTimeWindowMode.OFF)
            .maximumWindowInMinutes(useFlexibleTimeWindow
                ? flexibleTimeWindowMinutes
                : null)

Scenarios

Scheduled Events

The following code example shows how to:

- Deploy a AWS CloudFormation stack with required resources.
- Create a EventBridge Scheduler schedule group.
- Create a one-time EventBridge Scheduler schedule with a flexible time window.
- Create a recurring EventBridge Scheduler schedule with a specified rate.
- Delete EventBridge Scheduler the schedule and schedule group.
- Clean up resources and delete the stack.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run the scenario.

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.services.scheduler.model.SchedulerException;
import javax.mail.internet.AddressException;
import javax.mail.internet.InternetAddress;
import java.time.LocalDateTime;
import java.time.format.DateTimeFormatter;
import java.util.Map;
import java.util.Scanner;
import java.util.concurrent.CompletableFuture;
import java.util.concurrent.CompletionException;

/**
 * This Java code example performs the following tasks for the Amazon EventBridge
 Scheduler workflow:
 * <p>
 * 1. Prepare the Application:
```

```
 * - Prompt the user for an email address to use for the subscription for the SNS
 topic subscription.
 * - Deploy the Cloud Formation template in resources/cfn_template.yaml for resource
 creation.
 * - Store the outputs of the stack into variables for use in the workflow.
 * - Create a schedule group for all workflow schedules.
 * <p>
 * 2. Create one-time Schedule:
 * - Create a one-time schedule to send an initial event.
 * - Use a Flexible Time Window and set the schedule to delete after completion.
 * - Wait for the user to receive the event email from SNS.
 * <p>
 * 3. Create a time-based schedule:
 * - Prompt the user for how many X times per Y hours a recurring event should be
 scheduled.
 * - Create the scheduled event for X times per hour for Y hours.
 * - Wait for the user to receive the event email from SNS.
 * - Delete the schedule when the user is finished.
 * <p>
 * 4. Clean up:
 * - Prompt the user for y/n answer if they want to destroy the stack and clean up
 all resources.
 * - Delete the schedule group.
 * - Destroy the Cloud Formation stack and wait until the stack has been removed.

       logger.info("""
           Amazon EventBridge Scheduler is a fully managed service that helps you
schedule and execute
           a wide range of tasks and events in the cloud. It's designed to simplify
the process of
           scheduling and managing recurring or one-time events, making it easier
for developers and
           businesses to automate various workflows and processes.

           One of the key features of Amazon EventBridge Scheduler is its ability
to schedule events
           based on a variety of triggers, including time-based schedules, custom
event patterns, or
           even integration with other AWS services. For example, you can use
EventBridge Scheduler
           to schedule a report generation task to run every weekday at 9 AM, or to
trigger a
           Lambda function when a specific Amazon S3 object is created.

           This flexibility allows you to build complex and dynamic event-driven
architectures
           that adapt to your business needs.

           Lets get started...

Forecast examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Forecast.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

AWS Glue examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with AWS Glue.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello AWS Glue

The following code examples show how to get started using AWS Glue.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
package com.example.glue;

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.glue.GlueClient;
import software.amazon.awssdk.services.glue.model.ListJobsRequest;
import software.amazon.awssdk.services.glue.model.ListJobsResponse;
import java.util.List;

public class HelloGlue {
    public static void main(String[] args) {
        GlueClient glueClient = GlueClient.builder()
                .region(Region.US_EAST_1)
                .build();

        listJobs(glueClient);
    }

    public static void listJobs(GlueClient glueClient) {
        ListJobsRequest request = ListJobsRequest.builder()
                .maxResults(10)
                .build();
        ListJobsResponse response = glueClient.listJobs(request);
        List<String> jobList = response.jobNames();
        jobList.forEach(job -> {
            System.out.println("Job Name: " + job);
        });
    }
}
```

- For API details, see ListJobs in *AWS SDK for Java 2.x API Reference*.

Topics

- Basics
- Actions

Basics

Learn the basics

The following code example shows how to:

- Create a crawler that crawls a public Amazon S3 bucket and generates a database of CSV-formatted metadata.
- List information about databases and tables in your AWS Glue Data Catalog.
- Create a job to extract CSV data from the S3 bucket, transform the data, and load JSON-formatted output into another S3 bucket.
- List information about job runs, view transformed data, and clean up resources.

For more information, see Tutorial: Getting started with AWS Glue Studio.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 * <p>
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * To set up the resources, see this documentation topic:
 *
 * https://docs.aws.amazon.com/glue/latest/ug/tutorial-add-crawler.html
 *
```

```
 * This example performs the following tasks:
 *
 * 1. Create a database.
 * 2. Create a crawler.
 * 3. Get a crawler.
 * 4. Start a crawler.
 * 5. Get a database.
 * 6. Get tables.
 * 7. Create a job.
 * 8. Start a job run.
 * 9. List all jobs.
 * 10. Get job runs.
 * 11. Delete a job.
 * 12. Delete a database.
 * 13. Delete a crawler.
 */

public class GlueScenario {
    public static final String DASHES = new String(new char[80]).replace("\0", "-");

        System.out.println("""
            AWS Glue is a fully managed extract, transform, and load (ETL) service
provided by Amazon
            Web Services (AWS). It is designed to simplify the process of building,
running, and maintaining
            ETL pipelines, which are essential for data integration and data
warehousing tasks.

            One of the key features of AWS Glue is its ability to automatically
discover and catalog data
            stored in various sources, such as Amazon S3, Amazon RDS, Amazon
Redshift, and other databases.
            This cataloging process creates a central metadata repository, known as
the AWS Glue Data Catalog,
            which provides a unified view of an organization's data assets. This
metadata can then be used to
            create ETL jobs, which can be scheduled and run on-demand or on a
regular basis.

            Lets get started.

HealthImaging examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with HealthImaging.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions
- Scenarios

Actions

`CopyImageSet`

The following code example shows how to use `CopyImageSet`.

SDK for Java 2.x

```
/**
 * Copy an AWS HealthImaging image set.
 *
 * @param medicalImagingClient  - The AWS HealthImaging client object.
 * @param datastoreId           - The datastore ID.
 * @param imageSetId            - The image set ID.
 * @param latestVersionId       - The version ID.
```

```
    * @param destinationImageSetId - The optional destination image set ID, ignored
if null.
    * @param destinationVersionId  - The optional destination version ID, ignored
if null.
    * @param force                 - The force flag.
    * @param subsets               - The optional subsets to copy, ignored if null.
    * @return                      - The image set ID of the copy.
    * @throws MedicalImagingException - Base exception for all service exceptions
thrown by AWS HealthImaging.
    */

`GetDICOMImportJob`

The following code example shows how to use `GetDICOMImportJob`.

SDK for Java 2.x

```
   public static DICOMImportJobProperties getDicomImportJob(MedicalImagingClient
medicalImagingClient,
           String datastoreId,
           String jobId) {

       try {
           GetDicomImportJobRequest getDicomImportJobRequest =
GetDicomImportJobRequest.builder()
                   .datastoreId(datastoreId)
                   .jobId(jobId)
                   .build();
           GetDicomImportJobResponse response =
medicalImagingClient.getDICOMImportJob(getDicomImportJobRequest);
           return response.jobProperties();
       } catch (MedicalImagingException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }

       return null;
   }
```

- For API details, see GetDICOMImportJob in *AWS SDK for Java 2.x API Reference*.

`GetDatastore`

The following code example shows how to use `GetDatastore`.

SDK for Java 2.x

```
   public static DatastoreProperties getMedicalImageDatastore(MedicalImagingClient
medicalImagingClient,
           String datastoreID) {
       try {
           GetDatastoreRequest datastoreRequest = GetDatastoreRequest.builder()
                   .datastoreId(datastoreID)
                   .build();
           GetDatastoreResponse response =
medicalImagingClient.getDatastore(datastoreRequest);
           return response.datastoreProperties();
       } catch (MedicalImagingException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }

       return null;
   }
```

- For API details, see GetDatastore in *AWS SDK for Java 2.x API Reference*.

`GetImageFrame`

The following code example shows how to use `GetImageFrame`.

SDK for Java 2.x

```
       public static void getMedicalImageSetFrame(MedicalImagingClient
medicalImagingClient,
                       String destinationPath,
```

```
                        String datastoreId,
                        String imagesetId,
                        String imageFrameId) {

                try {
                        GetImageFrameRequest getImageSetMetadataRequest =
GetImageFrameRequest.builder()
                                        .datastoreId(datastoreId)
                                        .imageSetId(imagesetId)

.imageFrameInformation(ImageFrameInformation.builder()
                                                        .imageFrameId(imageFrameId)
                                                        .build())
                                        .build();

medicalImagingClient.getImageFrame(getImageSetMetadataRequest,

FileSystems.getDefault().getPath(destinationPath));

                        System.out.println("Image frame downloaded to " +
destinationPath);
                } catch (MedicalImagingException e) {
                        System.err.println(e.awsErrorDetails().errorMessage());
                        System.exit(1);
                }
        }
```

- For API details, see GetImageFrame in *AWS SDK for Java 2.x API Reference*.

`GetImageSet`

The following code example shows how to use `GetImageSet`.

SDK for Java 2.x

```
   public static GetImageSetResponse getMedicalImageSet(MedicalImagingClient
medicalImagingClient,
           String datastoreId,
           String imagesetId,
           String versionId) {
       try {
           GetImageSetRequest.Builder getImageSetRequestBuilder =
GetImageSetRequest.builder()
                   .datastoreId(datastoreId)
                   .imageSetId(imagesetId);

           if (versionId != null) {
               getImageSetRequestBuilder =
getImageSetRequestBuilder.versionId(versionId);
           }

           return
medicalImagingClient.getImageSet(getImageSetRequestBuilder.build());
       } catch (MedicalImagingException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }

       return null;
   }
```

- For API details, see GetImageSet in *AWS SDK for Java 2.x API Reference*.

> **Note**

`GetImageSetMetadata`

The following code example shows how to use `GetImageSetMetadata`.

SDK for Java 2.x

```
   public static void getMedicalImageSetMetadata(MedicalImagingClient
medicalImagingClient,
           String destinationPath,
           String datastoreId,
           String imagesetId,
           String versionId) {

       try {
           GetImageSetMetadataRequest.Builder getImageSetMetadataRequestBuilder =
GetImageSetMetadataRequest.builder()
                   .datastoreId(datastoreId)
                   .imageSetId(imagesetId);

           if (versionId != null) {
               getImageSetMetadataRequestBuilder =
getImageSetMetadataRequestBuilder.versionId(versionId);
           }

medicalImagingClient.getImageSetMetadata(getImageSetMetadataRequestBuilder.build(),
                   FileSystems.getDefault().getPath(destinationPath));

           System.out.println("Metadata downloaded to " + destinationPath);
       } catch (MedicalImagingException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see GetImageSetMetadata in *AWS SDK for Java 2.x API Reference*.

> **Note**

`ListDatastores`

The following code example shows how to use `ListDatastores`.

SDK for Java 2.x

```
   public static List<DatastoreSummary>
listMedicalImagingDatastores(MedicalImagingClient medicalImagingClient) {
       try {
           ListDatastoresRequest datastoreRequest = ListDatastoresRequest.builder()
                   .build();
           ListDatastoresIterable responses =
medicalImagingClient.listDatastoresPaginator(datastoreRequest);
           List<DatastoreSummary> datastoreSummaries = new ArrayList<>();

           responses.stream().forEach(response ->
datastoreSummaries.addAll(response.datastoreSummaries()));

           return datastoreSummaries;
       } catch (MedicalImagingException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }

       return null;
   }
```

- For API details, see ListDatastores in *AWS SDK for Java 2.x API Reference*.

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

`ListImageSetVersions`

The following code example shows how to use `ListImageSetVersions`.

SDK for Java 2.x

```
   public static List<ImageSetProperties>
listMedicalImageSetVersions(MedicalImagingClient medicalImagingClient,
           String datastoreId,
           String imagesetId) {
```

```
        try {
            ListImageSetVersionsRequest getImageSetRequest =
ListImageSetVersionsRequest.builder()
                    .datastoreId(datastoreId)
                    .imageSetId(imagesetId)
                    .build();

            ListImageSetVersionsIterable responses = medicalImagingClient
                    .listImageSetVersionsPaginator(getImageSetRequest);
            List<ImageSetProperties> imageSetProperties = new ArrayList<>();
            responses.stream().forEach(response ->
imageSetProperties.addAll(response.imageSetPropertiesList()));

            return imageSetProperties;
        } catch (MedicalImagingException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }

        return null;
    }
```

- For API details, see ListImageSetVersions in *AWS SDK for Java 2.x API Reference*.

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

`ListTagsForResource`

The following code example shows how to use `ListTagsForResource`.

SDK for Java 2.x

```
    public static ListTagsForResourceResponse
listMedicalImagingResourceTags(MedicalImagingClient medicalImagingClient,
            String resourceArn) {
        try {
            ListTagsForResourceRequest listTagsForResourceRequest =
ListTagsForResourceRequest.builder()
```

```
                    .resourceArn(resourceArn)
                    .build();

            return
medicalImagingClient.listTagsForResource(listTagsForResourceRequest);
        } catch (MedicalImagingException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }

        return null;
    }
```

- For API details, see ListTagsForResource in *AWS SDK for Java 2.x API Reference*.

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

`SearchImageSets`

The following code example shows how to use `SearchImageSets`.

SDK for Java 2.x

The utility function for searching image sets.

```
    public static List<ImageSetsMetadataSummary> searchMedicalImagingImageSets(
            MedicalImagingClient medicalImagingClient,
            String datastoreId, SearchCriteria searchCriteria) {
        try {
            SearchImageSetsRequest datastoreRequest =
SearchImageSetsRequest.builder()
                    .datastoreId(datastoreId)
                    .searchCriteria(searchCriteria)
                    .build();
            SearchImageSetsIterable responses = medicalImagingClient
                    .searchImageSetsPaginator(datastoreRequest);
            List<ImageSetsMetadataSummary> imageSetsMetadataSummaries = new
ArrayList<>();
```

```
            responses.stream().forEach(response -> imageSetsMetadataSummaries
                    .addAll(response.imageSetsMetadataSummaries()));

            return imageSetsMetadataSummaries;
        } catch (MedicalImagingException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }

        return null;
    }
```

Use case #1: EQUAL operator.

```
        List<SearchFilter> searchFilters =
Collections.singletonList(SearchFilter.builder()
                .operator(Operator.EQUAL)
                .values(SearchByAttributeValue.builder()
                        .dicomPatientId(patientId)
                        .build())
                .build());

        SearchCriteria searchCriteria = SearchCriteria.builder()
                .filters(searchFilters)
                .build();

        List<ImageSetsMetadataSummary> imageSetsMetadataSummaries =
searchMedicalImagingImageSets(
                medicalImagingClient,
                datastoreId, searchCriteria);
        if (imageSetsMetadataSummaries != null) {
            System.out.println("The image sets for patient " + patientId + " are:\n"
                    + imageSetsMetadataSummaries);
            System.out.println();
        }
```

Use case #2: BETWEEN operator using DICOMStudyDate and DICOMStudyTime.

```
        DateTimeFormatter formatter = DateTimeFormatter.ofPattern("yyyyMMdd");
        searchFilters = Collections.singletonList(SearchFilter.builder()
```

```
                .operator(Operator.BETWEEN)
                .values(SearchByAttributeValue.builder()

.dicomStudyDateAndTime(DICOMStudyDateAndTime.builder()
                                        .dicomStudyDate("19990101")
                                        .dicomStudyTime("000000.000")
                                        .build())
                                .build(),
                        SearchByAttributeValue.builder()

.dicomStudyDateAndTime(DICOMStudyDateAndTime.builder()
                                        .dicomStudyDate((LocalDate.now()
                                                .format(formatter)))
                                        .dicomStudyTime("000000.000")
                                        .build())
                                .build())
                .build());

        searchCriteria = SearchCriteria.builder()
                .filters(searchFilters)
                .build();

        imageSetsMetadataSummaries =
searchMedicalImagingImageSets(medicalImagingClient,
                datastoreId, searchCriteria);
        if (imageSetsMetadataSummaries != null) {
            System.out.println(
                    "The image sets searched with BETWEEN operator using
DICOMStudyDate and DICOMStudyTime are:\n"
                            +
                            imageSetsMetadataSummaries);
            System.out.println();
        }
```

Use case #3: BETWEEN operator using createdAt. Time studies were previously persisted.

```
        searchFilters = Collections.singletonList(SearchFilter.builder()
                .operator(Operator.BETWEEN)
                .values(SearchByAttributeValue.builder()
                                .createdAt(Instant.parse("1985-04-12T23:20:50.52Z"))
                                .build(),
                        SearchByAttributeValue.builder()
```

```
                                .createdAt(Instant.now())
                                .build())
                .build());

        searchCriteria = SearchCriteria.builder()
                .filters(searchFilters)
                .build();
        imageSetsMetadataSummaries =
searchMedicalImagingImageSets(medicalImagingClient,
                datastoreId, searchCriteria);
        if (imageSetsMetadataSummaries != null) {
            System.out.println("The image sets searched with BETWEEN operator using
createdAt are:\n "
                    + imageSetsMetadataSummaries);
            System.out.println();
        }
```

Use case #4: EQUAL operator on DICOMSeriesInstanceUID and BETWEEN on updatedAt and sort response in ASC order on updatedAt field.

```
        Instant startDate = Instant.parse("1985-04-12T23:20:50.52Z");
        Instant endDate = Instant.now();

        searchFilters = Arrays.asList(
                SearchFilter.builder()
                        .operator(Operator.EQUAL)
                        .values(SearchByAttributeValue.builder()
                                .dicomSeriesInstanceUID(seriesInstanceUID)
                                .build())
                        .build(),
                SearchFilter.builder()
                        .operator(Operator.BETWEEN)
                        .values(

SearchByAttributeValue.builder().updatedAt(startDate).build(),

SearchByAttributeValue.builder().updatedAt(endDate).build()
                        ).build());

        Sort sort =
Sort.builder().sortOrder(SortOrder.ASC).sortField(SortField.UPDATED_AT).build();
```

```
        searchCriteria = SearchCriteria.builder()
                .filters(searchFilters)
                .sort(sort)
                .build();

        imageSetsMetadataSummaries =
searchMedicalImagingImageSets(medicalImagingClient,
                datastoreId, searchCriteria);
        if (imageSetsMetadataSummaries != null) {
            System.out.println("The image sets searched with EQUAL operator on
DICOMSeriesInstanceUID and BETWEEN on updatedAt and sort response\n" +
                    "in ASC order on updatedAt field are:\n "
                    + imageSetsMetadataSummaries);
            System.out.println();
        }
```

`StartDICOMImportJob`

The following code example shows how to use `StartDICOMImportJob`.

SDK for Java 2.x

```
   public static String startDicomImportJob(MedicalImagingClient
medicalImagingClient,
            String jobName,
            String datastoreId,
            String dataAccessRoleArn,
            String inputS3Uri,
            String outputS3Uri) {

        try {
            StartDicomImportJobRequest startDicomImportJobRequest =
StartDicomImportJobRequest.builder()
```

```
                    .jobName(jobName)
                    .datastoreId(datastoreId)
                    .dataAccessRoleArn(dataAccessRoleArn)
                    .inputS3Uri(inputS3Uri)
                    .outputS3Uri(outputS3Uri)
                    .build();
            StartDicomImportJobResponse response =
medicalImagingClient.startDICOMImportJob(startDicomImportJobRequest);
            return response.jobId();
        } catch (MedicalImagingException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }

        return "";
    }
```

- For API details, see StartDICOMImportJob in *AWS SDK for Java 2.x API Reference*.

`TagResource`

The following code example shows how to use `TagResource`.

SDK for Java 2.x

```
    public static void tagMedicalImagingResource(MedicalImagingClient
medicalImagingClient,
            String resourceArn,
            Map<String, String> tags) {
        try {
            TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
                    .resourceArn(resourceArn)
                    .tags(tags)
                    .build();
```

```
            medicalImagingClient.tagResource(tagResourceRequest);

            System.out.println("Tags have been added to the resource.");
        } catch (MedicalImagingException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see TagResource in *AWS SDK for Java 2.x API Reference*.

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

`UntagResource`

The following code example shows how to use `UntagResource`.

SDK for Java 2.x

```
   public static void untagMedicalImagingResource(MedicalImagingClient
medicalImagingClient,
            String resourceArn,
            Collection<String> tagKeys) {
        try {
            UntagResourceRequest untagResourceRequest =
UntagResourceRequest.builder()
                    .resourceArn(resourceArn)
                    .tagKeys(tagKeys)
                    .build();

            medicalImagingClient.untagResource(untagResourceRequest);

            System.out.println("Tags have been removed from the resource.");
        } catch (MedicalImagingException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see UntagResource in *AWS SDK for Java 2.x API Reference*.

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

`UpdateImageSetMetadata`

The following code example shows how to use `UpdateImageSetMetadata`.

SDK for Java 2.x

```
   /**
    * Update the metadata of an AWS HealthImaging image set.
    *
    * @param medicalImagingClient - The AWS HealthImaging client object.
    * @param datastoreId          - The datastore ID.
    * @param imageSetId           - The image set ID.
    * @param versionId            - The version ID.
    * @param metadataUpdates      - A MetadataUpdates object containing the
updates.
    * @param force                - The force flag.
    * @throws MedicalImagingException - Base exception for all service exceptions
thrown by AWS HealthImaging.
    */
   public static void updateMedicalImageSetMetadata(MedicalImagingClient
medicalImagingClient,
                                                    String datastoreId,
                                                    String imageSetId,
                                                    String versionId,
                                                    MetadataUpdates
metadataUpdates,
                                                    boolean force) {
       try {
           UpdateImageSetMetadataRequest updateImageSetMetadataRequest =
UpdateImageSetMetadataRequest
                   .builder()
                   .datastoreId(datastoreId)
```

```
                    .imageSetId(imageSetId)
                    .latestVersionId(versionId)
                    .updateImageSetMetadataUpdates(metadataUpdates)
                    .force(force)
                    .build();

            UpdateImageSetMetadataResponse response =
medicalImagingClient.updateImageSetMetadata(updateImageSetMetadataRequest);

            System.out.println("The image set metadata was updated" + response);
        } catch (MedicalImagingException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            throw e;
        }
    }
```

Use case #1: Insert or update an attribute.

```
                final String insertAttributes = """
                        {
                          "SchemaVersion": 1.1,
                          "Study": {
                            "DICOM": {

Scenarios

Tagging a data store

The following code example shows how to tag a HealthImaging data store.

SDK for Java 2.x

To tag a data store.

```
                final String datastoreArn = "arn:aws:medical-imaging:us-
east-1:123456789012:datastore/12345678901234567890123456789012";

                TagResource.tagMedicalImagingResource(medicalImagingClient,
 datastoreArn,
                                ImmutableMap.of("Deployment", "Development"));
```

The utility function for tagging a resource.

```
   public static void tagMedicalImagingResource(MedicalImagingClient
 medicalImagingClient,
            String resourceArn,
            Map<String, String> tags) {
        try {
            TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
                    .resourceArn(resourceArn)
                    .tags(tags)
                    .build();

            medicalImagingClient.tagResource(tagResourceRequest);

            System.out.println("Tags have been added to the resource.");
        } catch (MedicalImagingException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

To list tags for a data store.

```
                final String datastoreArn = "arn:aws:medical-imaging:us-
east-1:123456789012:datastore/12345678901234567890123456789012";

                ListTagsForResourceResponse result =
 ListTagsForResource.listMedicalImagingResourceTags(
                                medicalImagingClient,
                                datastoreArn);
                if (result != null) {
                        System.out.println("Tags for resource: " + result.tags());
                }
```

The utility function for listing a resource's tags.

```
   public static ListTagsForResourceResponse
listMedicalImagingResourceTags(MedicalImagingClient medicalImagingClient,
           String resourceArn) {
       try {
           ListTagsForResourceRequest listTagsForResourceRequest =
ListTagsForResourceRequest.builder()
                   .resourceArn(resourceArn)
                   .build();

           return
medicalImagingClient.listTagsForResource(listTagsForResourceRequest);
       } catch (MedicalImagingException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }

       return null;
   }
```

To untag a data store.

```
               final String datastoreArn = "arn:aws:medical-imaging:us-
east-1:123456789012:datastore/12345678901234567890123456789012";

               UntagResource.untagMedicalImagingResource(medicalImagingClient,
 datastoreArn,
                               Collections.singletonList("Deployment"));
```

The utility function for untagging a resource.

```
   public static void untagMedicalImagingResource(MedicalImagingClient
medicalImagingClient,
           String resourceArn,
           Collection<String> tagKeys) {
       try {
```

```
            UntagResourceRequest untagResourceRequest =
UntagResourceRequest.builder()
                    .resourceArn(resourceArn)
                    .tagKeys(tagKeys)
                    .build();

            medicalImagingClient.untagResource(untagResourceRequest);

            System.out.println("Tags have been removed from the resource.");
        } catch (MedicalImagingException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Tagging an image set

The following code example shows how to tag a HealthImaging image set.

SDK for Java 2.x

To tag an image set.

```
                final String imageSetArn = "arn:aws:medical-imaging:us-
east-1:123456789012:datastore/12345678901234567890123456789012/
imageset/12345678901234567890123456789012";

                TagResource.tagMedicalImagingResource(medicalImagingClient,
 imageSetArn,
```

```
                                ImmutableMap.of("Deployment", "Development"));
```

The utility function for tagging a resource.

```
   public static void tagMedicalImagingResource(MedicalImagingClient
medicalImagingClient,
           String resourceArn,
           Map<String, String> tags) {
       try {
           TagResourceRequest tagResourceRequest = TagResourceRequest.builder()
                   .resourceArn(resourceArn)
                   .tags(tags)
                   .build();

           medicalImagingClient.tagResource(tagResourceRequest);

           System.out.println("Tags have been added to the resource.");
       } catch (MedicalImagingException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

To list tags for an image set.

```
               final String imageSetArn = "arn:aws:medical-imaging:us-
east-1:123456789012:datastore/12345678901234567890123456789012/
imageset/12345678901234567890123456789012";

               ListTagsForResourceResponse result =
ListTagsForResource.listMedicalImagingResourceTags(
                               medicalImagingClient,
                               imageSetArn);
               if (result != null) {
                       System.out.println("Tags for resource: " + result.tags());
               }
```

The utility function for listing a resource's tags.

```
   public static ListTagsForResourceResponse
listMedicalImagingResourceTags(MedicalImagingClient medicalImagingClient,
           String resourceArn) {
       try {
           ListTagsForResourceRequest listTagsForResourceRequest =
ListTagsForResourceRequest.builder()
                   .resourceArn(resourceArn)
                   .build();

           return
medicalImagingClient.listTagsForResource(listTagsForResourceRequest);
       } catch (MedicalImagingException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }

       return null;
   }
```

To untag an image set.

```
               final String imageSetArn = "arn:aws:medical-imaging:us-
east-1:123456789012:datastore/12345678901234567890123456789012/
imageset/12345678901234567890123456789012";

               UntagResource.untagMedicalImagingResource(medicalImagingClient,
 imageSetArn,
                               Collections.singletonList("Deployment"));
```

The utility function for untagging a resource.

```
   public static void untagMedicalImagingResource(MedicalImagingClient
medicalImagingClient,
           String resourceArn,
           Collection<String> tagKeys) {
       try {
           UntagResourceRequest untagResourceRequest =
UntagResourceRequest.builder()
                   .resourceArn(resourceArn)
                   .tagKeys(tagKeys)
```

```
                .build();

        medicalImagingClient.untagResource(untagResourceRequest);

        System.out.println("Tags have been removed from the resource.");
    } catch (MedicalImagingException e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

IAM examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with IAM.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello IAM

The following code examples show how to get started using IAM.

SDK for Java 2.x

- Scenarios

Basics

Learn the basics

The following code example shows how to create a user and assume a role.

> **Warning**
>
> To avoid security risks, don't use IAM users for authentication when developing purpose-built software or working with real data. Instead, use federation with an identity provider such as AWS IAM Identity Center.

- Create a user with no permissions.
- Create a role that grants permission to list Amazon S3 buckets for the account.
- Add a policy to let the user assume the role.
- Assume the role and list S3 buckets using temporary credentials, then clean up resources.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Create functions that wrap IAM user actions.

```
/*
  To run this Java V2 code example, set up your development environment, including
 your credentials.

  For information, see this documentation topic:

  https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html

  This example performs these operations:

  1. Creates a user that has no permissions.
  2. Creates a role and policy that grants Amazon S3 permissions.
  3. Creates a role.
  4. Grants the user permissions.
  5. Gets temporary credentials by assuming the role.  Creates an Amazon S3 Service
 client object with the temporary credentials.
  6. Deletes the resources.
 */

Scenarios

Build and manage a resilient service

The following code example shows how to create a load-balanced web service that returns book, movie, and song recommendations. The example shows how the service responds to failures, and how to restructure the service for more resilience when failures occur.

- Use an Amazon EC2 Auto Scaling group to create Amazon Elastic Compute Cloud (Amazon EC2) instances based on a launch template and to keep the number of instances in a specified range.
- Handle and distribute HTTP requests with Elastic Load Balancing.
- Monitor the health of instances in an Auto Scaling group and forward requests only to healthy instances.
- Run a Python web server on each EC2 instance to handle HTTP requests. The web server responds with recommendations and health checks.
- Simulate a recommendation service with an Amazon DynamoDB table.
- Control web server response to requests and health checks by updating AWS Systems Manager parameters.

                    .keySchema(
                            KeySchemaElement.builder()
                                    .attributeName("MediaType")
                                    .keyType(KeyType.HASH)
                                    .build(),
                            KeySchemaElement.builder()
                                    .attributeName("ItemId")
                                    .keyType(KeyType.RANGE)
                                    .build())
                    .provisionedThroughput(
                            ProvisionedThroughput.builder()
                                    .readCapacityUnits(5L)
                                    .writeCapacityUnits(5L)
                                    .build())
                    .build();

            getDynamoDbClient().createTable(createTableRequest);
            System.out.println("Creating table " + tableName + "...");

            // Wait until the Amazon DynamoDB table is created.
            DescribeTableRequest tableRequest = DescribeTableRequest.builder()
                    .tableName(tableName)
                    .build();
```

```
            WaiterResponse<DescribeTableResponse> waiterResponse =
dbWaiter.waitUntilTableExists(tableRequest);
            waiterResponse.matched().response().ifPresent(System.out::println);
            System.out.println("Table " + tableName + " created.");

            // Add records to the table.
            populateTable(fileName, tableName);
        }
    }

    public void deleteTable(String tableName) {
        getDynamoDbClient().deleteTable(table -> table.tableName(tableName));
        System.out.println("Table " + tableName + " deleted.");
    }

    // Populates the table with data located in a JSON file using the DynamoDB
    // enhanced client.
    public void populateTable(String fileName, String tableName) throws IOException
{
        DynamoDbEnhancedClient enhancedClient = DynamoDbEnhancedClient.builder()
                .dynamoDbClient(getDynamoDbClient())
                .build();
        ObjectMapper objectMapper = new ObjectMapper();
        File jsonFile = new File(fileName);
        JsonNode rootNode = objectMapper.readTree(jsonFile);

        DynamoDbTable<Recommendation> mappedTable = enhancedClient.table(tableName,
                TableSchema.fromBean(Recommendation.class));
        for (JsonNode currentNode : rootNode) {
            String mediaType = currentNode.path("MediaType").path("S").asText();
            int itemId = currentNode.path("ItemId").path("N").asInt();
            String title = currentNode.path("Title").path("S").asText();
            String creator = currentNode.path("Creator").path("S").asText();

            // Create a Recommendation object and set its properties.
            Recommendation rec = new Recommendation();
            rec.setMediaType(mediaType);
            rec.setItemId(itemId);
            rec.setTitle(title);
            rec.setCreator(creator);

            // Put the item into the DynamoDB table.
            mappedTable.putItem(rec); // Add the Recommendation to the list.
        }
```

```
        System.out.println("Added all records to the " + tableName);
    }
}
```

Create a class that wraps Systems Manager actions.

```
public class ParameterHelper {

    String tableName = "doc-example-resilient-architecture-table";
    String dyntable = "doc-example-recommendation-service";
    String failureResponse = "doc-example-resilient-architecture-failure-response";
    String healthCheck = "doc-example-resilient-architecture-health-check";

    public void reset() {
        put(dyntable, tableName);
        put(failureResponse, "none");
        put(healthCheck, "shallow");
    }

    public void put(String name, String value) {
        SsmClient ssmClient = SsmClient.builder()
                .region(Region.US_EAST_1)
                .build();

        PutParameterRequest parameterRequest = PutParameterRequest.builder()
                .name(name)
                .value(value)
                .overwrite(true)
                .type("String")
                .build();

        ssmClient.putParameter(parameterRequest);
        System.out.printf("Setting demo parameter %s to '%s'.", name, value);
    }
}
```

Work with the IAM Policy Builder API

The following code example shows how to:

- Create IAM policies by using the object-oriented API.
- Use the IAM Policy Builder API with the IAM service.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

The examples use the following imports.

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.policybuilder.iam.IamConditionOperator;
import software.amazon.awssdk.policybuilder.iam.IamEffect;
import software.amazon.awssdk.policybuilder.iam.IamPolicy;
import software.amazon.awssdk.policybuilder.iam.IamPolicyWriter;
import software.amazon.awssdk.policybuilder.iam.IamPrincipal;
import software.amazon.awssdk.policybuilder.iam.IamPrincipalType;
import software.amazon.awssdk.policybuilder.iam.IamResource;
import software.amazon.awssdk.policybuilder.iam.IamStatement;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iam.IamClient;
import software.amazon.awssdk.services.iam.model.GetPolicyResponse;
import software.amazon.awssdk.services.iam.model.GetPolicyVersionResponse;
import software.amazon.awssdk.services.sts.StsClient;

import java.net.URLDecoder;
import java.nio.charset.StandardCharsets;
import java.util.Arrays;
import java.util.List;
```

Create a time-based policy.

```
        public String timeBasedPolicyExample() {
                IamPolicy policy = IamPolicy.builder()
                                .addStatement(b -> b
                                                .effect(IamEffect.ALLOW)
                                                .addAction("dynamodb:GetItem")
                                                .addResource(IamResource.ALL)
                                                .addCondition(b1 -> b1
```

```
.operator(IamConditionOperator.DATE_GREATER_THAN)

.key("aws:CurrentTime")

.value("2020-04-01T00:00:00Z"))
                                                .addCondition(b1 -> b1

.operator(IamConditionOperator.DATE_LESS_THAN)

.key("aws:CurrentTime")

.value("2020-06-30T23:59:59Z")))
                                .build();

                // Use an IamPolicyWriter to write out the JSON string to a more
readable
                // format.
                return policy.toJson(IamPolicyWriter.builder()
                                .prettyPrint(true)
                                .build());
        }
```

Create a policy with multiple conditions.

```
        public String multipleConditionsExample() {
                IamPolicy policy = IamPolicy.builder()
                                .addStatement(b -> b
                                                .effect(IamEffect.ALLOW)
                                                .addAction("dynamodb:GetItem")
                                                .addAction("dynamodb:BatchGetItem")
                                                .addAction("dynamodb:Query")
                                                .addAction("dynamodb:PutItem")
                                                .addAction("dynamodb:UpdateItem")
                                                .addAction("dynamodb:DeleteItem")

.addAction("dynamodb:BatchWriteItem")

.addResource("arn:aws:dynamodb:*:*:table/table-name")

.addConditions(IamConditionOperator.STRING_EQUALS
```

```
 .addPrefix("ForAllValues:"),

 "dynamodb:Attributes",
                                                                    List.of("column-
name1", "column-name2", "column-name3"))
                                                .addCondition(b1 -> b1

 .operator(IamConditionOperator.STRING_EQUALS

 .addSuffix("IfExists"))

 .key("dynamodb:Select")

 .value("SPECIFIC_ATTRIBUTES")))
                                .build();

                return policy.toJson(IamPolicyWriter.builder()
                                .prettyPrint(true).build());
        }
```

Use principals in a policy.

```
        public String specifyPrincipalsExample() {
                IamPolicy policy = IamPolicy.builder()
                                .addStatement(b -> b
                                                .effect(IamEffect.DENY)
                                                .addAction("s3:*")
                                                .addPrincipal(IamPrincipal.ALL)
                                                .addResource("arn:aws:s3:::amzn-s3-
demo-bucket/*")
                                                .addResource("arn:aws:s3:::amzn-s3-
demo-bucket")
                                                .addCondition(b1 -> b1

 .operator(IamConditionOperator.ARN_NOT_EQUALS)

 .key("aws:PrincipalArn")

 .value("arn:aws:iam::444455556666:user/user-name")))
                                .build();
                return policy.toJson(IamPolicyWriter.builder()
```

```
                                .prettyPrint(true).build());
        }
```

Allow cross-account access.

```
        public String allowCrossAccountAccessExample() {
                IamPolicy policy = IamPolicy.builder()
                                .addStatement(b -> b
                                                .effect(IamEffect.ALLOW)
                                                .addPrincipal(IamPrincipalType.AWS,
 "111122223333")
                                                .addAction("s3:PutObject")
                                                .addResource("arn:aws:s3:::amzn-s3-
demo-bucket/*")
                                                .addCondition(b1 -> b1

 .operator(IamConditionOperator.STRING_EQUALS)
                                                                .key("s3:x-amz-acl")
                                                                .value("bucket-
owner-full-control")))
                                .build();
                return policy.toJson(IamPolicyWriter.builder()
                                .prettyPrint(true).build());
        }
```

Build and upload an `IamPolicy`.

```
        public String createAndUploadPolicyExample(IamClient iam, String accountID,
 String policyName) {
                // Build the policy.
                IamPolicy policy = IamPolicy.builder() // 'version' defaults to
 "2012-10-17".
                                .addStatement(IamStatement.builder()
                                                .effect(IamEffect.ALLOW)
                                                .addAction("dynamodb:PutItem")
                                                .addResource("arn:aws:dynamodb:us-
east-1:" + accountID
                                                                + ":table/
exampleTableName")
                                                .build())
                                .build();
```

```
                // Upload the policy.
                iam.createPolicy(r ->
r.policyName(policyName).policyDocument(policy.toJson()));
                return
policy.toJson(IamPolicyWriter.builder().prettyPrint(true).build());
        }
```

Download and work with an `IamPolicy`.

```
        public String createNewBasedOnExistingPolicyExample(IamClient iam, String
accountID, String policyName,
                        String newPolicyName) {

                String policyArn = "arn:aws:iam::" + accountID + ":policy/" +
policyName;
                GetPolicyResponse getPolicyResponse = iam.getPolicy(r ->
r.policyArn(policyArn));

                String policyVersion =
getPolicyResponse.policy().defaultVersionId();
                GetPolicyVersionResponse getPolicyVersionResponse = iam
                                .getPolicyVersion(r ->
r.policyArn(policyArn).versionId(policyVersion));

                // Create an IamPolicy instance from the JSON string returned from
IAM.
                String decodedPolicy =
URLDecoder.decode(getPolicyVersionResponse.policyVersion().document(),
                                StandardCharsets.UTF_8);
                IamPolicy policy = IamPolicy.fromJson(decodedPolicy);

                /*
                 * All IamPolicy components are immutable, so use the copy method
that creates a
                 * new instance that
                 * can be altered in the same method call.
                 *
                 * Add the ability to get an item from DynamoDB as an additional
action.
                 */
                IamStatement newStatement = policy.statements().get(0).copy(s ->
s.addAction("dynamodb:GetItem"));
```

```
                // Create a new statement that replaces the original statement.
                IamPolicy newPolicy = policy.copy(p ->
p.statements(Arrays.asList(newStatement)));

                // Upload the new policy. IAM now has both policies.
                iam.createPolicy(r -> r.policyName(newPolicyName)
                                .policyDocument(newPolicy.toJson()));

                return
newPolicy.toJson(IamPolicyWriter.builder().prettyPrint(true).build());
        }
```

AWS IoT examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with AWS IoT.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello AWS IoT

The following code examples show how to get started using AWS IoT.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.iot.IotClient;
import software.amazon.awssdk.services.iot.model.ListThingsRequest;
import software.amazon.awssdk.services.iot.model.ListThingsResponse;
import software.amazon.awssdk.services.iot.model.ThingAttribute;
import software.amazon.awssdk.services.iot.paginators.ListThingsIterable;

import java.util.List;

public class HelloIoT {
    public static void main(String[] args) {
        System.out.println("Hello AWS IoT. Here is a listing of your AWS IoT
 Things:");
        IotClient iotClient = IotClient.builder()
            .region(Region.US_EAST_1)
            .build();

        listAllThings(iotClient);
    }

    public static void listAllThings(IotClient iotClient) {
        iotClient.listThingsPaginator(ListThingsRequest.builder()
                .maxResults(10)
                .build())
            .stream()
            .flatMap(response -> response.things().stream())
            .forEach(attribute -> {
                System.out.println("Thing name: " + attribute.thingName());
                System.out.println("Thing ARN: " + attribute.thingArn());
            });
    }
}
```

- For API details, see listThings in *AWS SDK for Java 2.x API Reference*.

Topics

- Basics
- Actions

Basics

Learn the basics

The following code example shows how to:

- Create an AWS IoT Thing.
- Generate a device certificate.
- Update an AWS IoT Thing with Attributes.
- Return a unique endpoint.
- List your AWS IoT certificates.
- Create an AWS IoT shadow.
- Write out state information.
- Creates a rule.
- List your rules.
- Search things using the Thing name.
- Delete an AWS IoT Thing.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario demonstrating AWS IoT features.

```
import java.util.Scanner;
```

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * This Java example performs these tasks:
 *
 * 1. Creates an AWS IoT Thing.
 * 2. Generate and attach a device certificate.
 * 3. Update an AWS IoT Thing with Attributes.
 * 4. Get an AWS IoT Endpoint.
 * 5. List your certificates.
 * 6. Updates the shadow for the specified thing..
 * 7. Write out the state information, in JSON format
 * 8. Creates a rule

AWS IoT FleetWise examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with AWS IoT FleetWise.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello AWS IoT FleetWise

The following code examples show how to get started using AWS IoT FleetWise.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
public class HelloFleetwise {

        public static void main(String[] args) {
            ListSignalCatalogs();
        }

        public static void  ListSignalCatalogs() {
            try (IoTFleetWiseClient fleetWiseClient = IoTFleetWiseClient.builder()
                    .region(Region.US_EAST_1)
                    .credentialsProvider(DefaultCredentialsProvider.create())
                    .build()) {

                ListSignalCatalogsRequest request =
 ListSignalCatalogsRequest.builder()
                        .maxResults(10) // Optional: limit per page
                        .build();

                ListSignalCatalogsIterable paginator =
 fleetWiseClient.listSignalCatalogsPaginator(request);
                boolean found = false;
```

```
                for (ListSignalCatalogsResponse response : paginator) {
                    for (SignalCatalogSummary summary : response.summaries()) {
                        found = true;
                        System.out.println("Catalog Name: " + summary.name());
                        System.out.println("ARN: " + summary.arn());
                        System.out.println("Created: " + summary.creationTime());
                        System.out.println("Last Modified: " +
summary.lastModificationTime());
                        System.out.println("---------------");
                    }
                }

                if (!found) {
                    System.out.println("No AWS Fleetwise Signal Catalogs were
found.");
                }

            } catch (IoTFleetWiseException e) {
                System.err.println("Error listing signal catalogs: " +
e.awsErrorDetails().errorMessage());
                throw new RuntimeException(e);
            }
        }
    }
```

- For API details, see listSignalCatalogsPaginator in *AWS SDK for Java 2.x API Reference*.

Basics

Learn the basics

The following code example shows how to:

- Create a collection of standardized signals.
- Create a fleet that represents a group of vehicles.

- Create a model manifest.
- Create a decoder manifest.
- Check the status of the model manifest.
- Check the status of the decoder.
- Create an IoT Thing.
- Create a vehicle.
- Display vehicle details.
- Delete the AWS IoT FleetWise Assets.

SDK for Java 2.x

>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario demonstrating AWS IoT SiteWise features.

```
public class FleetwiseScenario {
    public static final String DASHES = new String(new char[80]).replace("\0", "-");
    static FleetwiseActions actions = new FleetwiseActions();
    private static final Logger logger =
 LoggerFactory.getLogger(FleetwiseScenario.class);
    static Scanner scanner = new Scanner(System.in);

    public static void main(String[] args) {
        final String usage =
                """
                Usage:
                    <signalCatalogName> <manifestName> <fleetId> <vecName> <decName>

                Where:
                    signalCatalogName     - The name of the Signal Catalog to create
 (eg, catalog30).
                    manifestName          - The name of the Vehicle Model (Model
 Manifest) to create (eg, manifest30).
                    fleetId               - The ID of the Fleet to create (eg,
 fleet30).
```

```
                    vecName               - The name of the Vehicle to create (eg,
vehicle30).
                    decName               - The name of the Decoder Manifest to
create (eg, decManifest30).
                """;

        if (args.length != 5) {
            logger.info(usage);
            return;
        }

        String signalCatalogName = args[0];
        String manifestName = args[1];
        String fleetId = args[2];
        String vecName = args[3];
        String decName = args[4];

        logger.info(
                """
                 AWS IoT FleetWise is a managed service that simplifies the
                 process of collecting, organizing, and transmitting vehicle
                 data to the cloud in near real-time. Designed for automakers
                 and fleet operators, it allows you to define vehicle models,
                 specify the exact data you want to collect (such as engine
                 temperature, speed, or battery status), and send this data to
                 AWS for analysis. By using intelligent data collection
                 techniques, IoT FleetWise reduces the volume of data
                 transmitted by filtering and transforming it at the edge,
                 helping to minimize bandwidth usage and costs.

                At its core, AWS IoT FleetWise helps organizations build
                scalable systems for vehicle data management and analytics,
                supporting a wide variety of vehicles and sensor configurations.
                You can define signal catalogs and decoder manifests that describe
                how raw CAN bus signals are translated into readable data, making
                the platform highly flexible and extensible. This allows
                manufacturers to optimize vehicle performance, improve safety,
                and reduce maintenance costs by gaining real-time visibility
                into fleet operations.
                """);

        waitForInputToContinue(scanner);
        logger.info(DASHES);

                       details.forEach((key, value) -> logger.info("• {} : {}",
key, value));

                       result.complete(null); // mark as successful
                   }
               });
```

```
        return result;
    }
```

- For API details, see getVehicle in *AWS SDK for Java 2.x API Reference*.

`listSignalCatalogNodes`

The following code example shows how to use `listSignalCatalogNodes`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /**
     * Asynchronously retrieves a list of all nodes in the specified signal catalog.
     *
     * @param signalCatalogName the name of the signal catalog to retrieve nodes for
     * @return a {@link CompletableFuture} that, when completed, contains a {@link
List} of {@link Node} objects
     * representing all the nodes in the specified signal catalog
     */
    public CompletableFuture<List<Node>> listSignalCatalogNodeAsync(String
signalCatalogName) {
        ListSignalCatalogNodesRequest request =
ListSignalCatalogNodesRequest.builder()
                .name(signalCatalogName)
                .build();

        List<Node> allNodes = new ArrayList<>();

        return getAsyncClient().listSignalCatalogNodesPaginator(request)
                .subscribe(response -> allNodes.addAll(response.nodes()))
                .thenApply(v -> allNodes);
    }
```

- For API details, see listSignalCatalogNodes in *AWS SDK for Java 2.x API Reference*.

`updateDecoderManifest`

The following code example shows how to use `updateDecoderManifest`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   /**
    * Updates the decoder manifest with the given name.
    *
    * @param name the name of the decoder manifest to update
    * @return a {@link CompletableFuture} that completes when the update operation
is finished
    */
   public CompletableFuture<Void> updateDecoderManifestAsync(String name) {
       UpdateDecoderManifestRequest request =
UpdateDecoderManifestRequest.builder()
               .name(name)
               .status(ManifestStatus.ACTIVE)
               .build();

       return getAsyncClient().updateDecoderManifest(request)
               .whenComplete((response, exception) -> {
                   if (exception != null) {
                       throw new CompletionException("Failed to update decoder
manifest: " + exception.getMessage(), exception);
                   }
               })
               .thenApply(response -> null);
   }
```

- For API details, see updateDecoderManifest in *AWS SDK for Java 2.x API Reference*.

`updateModelManifest`

The following code example shows how to use `updateModelManifest`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /**
     * Updates the model manifest.
     *

     */
    public void updateModelManifestAsync(String name) {
        UpdateModelManifestRequest request = UpdateModelManifestRequest.builder()
                .name(name)
                .status(ManifestStatus.ACTIVE)
                .build();

        getAsyncClient().updateModelManifest(request)
                .whenComplete((response, exception) -> {
                    if (exception != null) {
                        throw new CompletionException("Failed to update model
manifest: " + exception.getMessage(), exception);
                    }
                })
                .thenApply(response -> null);
    }
```

- For API details, see updateModelManifest in *AWS SDK for Java 2.x API Reference*.

AWS IoT SiteWise examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with AWS IoT SiteWise.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello AWS IoT SiteWise

The following code examples show how to get started using AWS IoT SiteWise.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
public class HelloSitewise {
    private static final Logger logger =
 LoggerFactory.getLogger(HelloSitewise.class);
    public static void main(String[] args) {
         fetchAssetModels();
    }

    /**
     * Fetches asset models using the provided {@link IoTSiteWiseAsyncClient}.
     */
    public static void fetchAssetModels() {
        IoTSiteWiseAsyncClient siteWiseAsyncClient =
 IoTSiteWiseAsyncClient.create();
        ListAssetModelsRequest assetModelsRequest = ListAssetModelsRequest.builder()
```

```
            .assetModelTypes(AssetModelType.ASSET_MODEL)
            .build();

        // Asynchronous paginator - process paginated results.
        ListAssetModelsPublisher listModelsPaginator =
 siteWiseAsyncClient.listAssetModelsPaginator(assetModelsRequest);
        CompletableFuture<Void> future = listModelsPaginator.subscribe(response -> {
            response.assetModelSummaries().forEach(assetSummary ->
                logger.info("Asset Model Name: {} ", assetSummary.name())
            );
        });

        // Wait for the asynchronous operation to complete
        future.join();
    }
}
```

- For API details, see ListAssetModels in *AWS SDK for Java 2.x API Reference*.

Topics

- Basics
- Actions

Basics

Learn the basics

The following code example shows how to:

- Create an AWS IoT SiteWise Asset Model.
- Create an AWS IoT SiteWise Asset.
- Retrieve the property ID values.
- Send data to an AWS IoT SiteWise Asset.
- Retrieve the value of the AWS IoT SiteWise Asset property.
- Create an AWS IoT SiteWise Portal.
- Create an AWS IoT SiteWise Gateway.
- Describe the AWS IoT SiteWise Gateway.

- Delete the AWS IoT SiteWise Assets.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario demonstrating AWS IoT SiteWise features.

```
public class SitewiseScenario {

    public static final String DASHES = new String(new char[80]).replace("\0", "-");

    private static final Logger logger =
 LoggerFactory.getLogger(SitewiseScenario.class);
    static Scanner scanner = new Scanner(System.in);

    private static final String ROLES_STACK = "RoleSitewise";

    static SitewiseActions sitewiseActions = new SitewiseActions();

    public static void main(String[] args) throws Throwable {
        Scanner scanner = new Scanner(System.in);
        String contactEmail = "user@mydomain.com"; // Change email address.
        String assetModelName = "MyAssetModel1";
        String assetName = "MyAsset1" ;
        String portalName = "MyPortal1" ;
        String gatewayName = "MyGateway1" ;
        String myThing =  "MyThing1" ;

        logger.info("""
            AWS IoT SiteWise is a fully managed software-as-a-service (SaaS) that
            makes it easy to collect, store, organize, and monitor data from
 industrial equipment and processes.
            It is designed to help industrial and manufacturing organizations
 collect data from their equipment and
            processes, and use that data to make informed decisions about their
 operations.
```

```
            One of the key features of AWS IoT SiteWise is its ability to connect to
a wide range of industrial
            equipment and systems, including programmable logic controllers (PLCs),
sensors, and other
            industrial devices. It can collect data from these devices and organize
it into a unified data model,
            making it easier to analyze and gain insights from the data. AWS IoT
SiteWise also provides tools for
            visualizing the data, setting up alarms and alerts, and generating
reports.

            Another key feature of AWS IoT SiteWise is its ability to scale to
handle large volumes of data.
            It can collect and store data from thousands of devices and process
millions of data points per second,
            making it suitable for large-scale industrial operations. Additionally,
AWS IoT SiteWise is designed
            to be secure and compliant, with features like role-based access
controls, data encryption,
            and integration with other AWS services for additional security and
compliance features.

            Let's get started...

Amazon Keyspaces examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Keyspaces.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon Keyspaces

The following code examples show how to get started using Amazon Keyspaces.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.keyspaces.KeyspacesClient;
import software.amazon.awssdk.services.keyspaces.model.KeyspaceSummary;
import software.amazon.awssdk.services.keyspaces.model.KeyspacesException;
import software.amazon.awssdk.services.keyspaces.model.ListKeyspacesRequest;
import software.amazon.awssdk.services.keyspaces.model.ListKeyspacesResponse;
import java.util.List;

/**
 * Before running this Java (v2) code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class HelloKeyspaces {
    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
        KeyspacesClient keyClient = KeyspacesClient.builder()
                .region(region)
                .build();

        listKeyspaces(keyClient);
    }

    public static void listKeyspaces(KeyspacesClient keyClient) {
        try {
            ListKeyspacesRequest keyspacesRequest = ListKeyspacesRequest.builder()
                    .maxResults(10)
                    .build();
```

```
            ListKeyspacesResponse response =
 keyClient.listKeyspaces(keyspacesRequest);
            List<KeyspaceSummary> keyspaces = response.keyspaces();
            for (KeyspaceSummary keyspace : keyspaces) {
                System.out.println("The name of the keyspace is " +
 keyspace.keyspaceName());
            }

        } catch (KeyspacesException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
}
```

- For API details, see ListKeyspaces in *AWS SDK for Java 2.x API Reference*.

Topics

- Basics
- Actions

Basics

Learn the basics

The following code example shows how to:

- Create a keyspace and table. The table schema holds movie data and has point-in-time recovery enabled.
- Connect to the keyspace using a secure TLS connection with SigV4 authentication.
- Query the table. Add, retrieve, and update movie data.
- Update the table. Add a column to track watched movies.
- Restore the table to its previous state and clean up resources.

 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * Before running this Java code example, you must create a
 * Java keystore (JKS) file and place it in your project's resources folder.
 *
 * This file is a secure file format used to hold certificate information for
 * Java applications. This is required to make a connection to Amazon Keyspaces.
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/keyspaces/latest/devguide/using_java_driver.html
 *
 * This Java example performs the following tasks:
 *
 * 1. Create a keyspace.
 * 2. Check for keyspace existence.
 * 3. List keyspaces using a paginator.
 * 4. Create a table with a simple movie data schema and enable point-in-time
 * recovery.
 * 5. Check for the table to be in an Active state.
 * 6. List all tables in the keyspace.
 * 7. Use a Cassandra driver to insert some records into the Movie table.
 * 8. Get all records from the Movie table.
 * 9. Get a specific Movie.
 * 10. Get a UTC timestamp for the current time.
 * 11. Update the table schema to add a ‘watched’ Boolean column.
 * 12. Update an item as watched.
 * 13. Query for items with watched = True.
 * 14. Restore the table back to the previous state using the timestamp.
```

```
 * 15. Check for completion of the restore action.
 * 16. Delete the table.
 * 17. Confirm that both tables are deleted.
 * 18. Delete the keyspace.
 */

Actions

`CreateKeyspace`

The following code example shows how to use `CreateKeyspace`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   public static void createKeySpace(KeyspacesClient keyClient, String
keyspaceName) {
       try {
           CreateKeyspaceRequest keyspaceRequest = CreateKeyspaceRequest.builder()
                   .keyspaceName(keyspaceName)
                   .build();

           CreateKeyspaceResponse response =
keyClient.createKeyspace(keyspaceRequest);
           System.out.println("The ARN of the KeySpace is " +
response.resourceArn());

       } catch (KeyspacesException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see CreateKeyspace in *AWS SDK for Java 2.x API Reference*.

`CreateTable`

The following code example shows how to use `CreateTable`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   public static void createTable(KeyspacesClient keyClient, String keySpace,
String tableName) {
       try {
           // Set the columns.
           ColumnDefinition defTitle = ColumnDefinition.builder()
                   .name("title")
                   .type("text")
                   .build();

           ColumnDefinition defYear = ColumnDefinition.builder()
                   .name("year")
                   .type("int")
                   .build();

           ColumnDefinition defReleaseDate = ColumnDefinition.builder()
                   .name("release_date")
                   .type("timestamp")
                   .build();

           ColumnDefinition defPlot = ColumnDefinition.builder()
                   .name("plot")
                   .type("text")
                   .build();

           List<ColumnDefinition> colList = new ArrayList<>();
           colList.add(defTitle);
           colList.add(defYear);
           colList.add(defReleaseDate);
           colList.add(defPlot);

           // Set the keys.
           PartitionKey yearKey = PartitionKey.builder()
                   .name("year")
                   .build();
```

```
            PartitionKey titleKey = PartitionKey.builder()
                    .name("title")
                    .build();

            List<PartitionKey> keyList = new ArrayList<>();
            keyList.add(yearKey);
            keyList.add(titleKey);

            SchemaDefinition schemaDefinition = SchemaDefinition.builder()
                    .partitionKeys(keyList)
                    .allColumns(colList)
                    .build();

            PointInTimeRecovery timeRecovery = PointInTimeRecovery.builder()
                    .status(PointInTimeRecoveryStatus.ENABLED)
                    .build();

            CreateTableRequest tableRequest = CreateTableRequest.builder()
                    .keyspaceName(keySpace)
                    .tableName(tableName)
                    .schemaDefinition(schemaDefinition)
                    .pointInTimeRecovery(timeRecovery)
                    .build();

            CreateTableResponse response = keyClient.createTable(tableRequest);
            System.out.println("The table ARN is " + response.resourceArn());

        } catch (KeyspacesException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see CreateTable in *AWS SDK for Java 2.x API Reference*.

`DeleteKeyspace`

The following code example shows how to use `DeleteKeyspace`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   public static void deleteKeyspace(KeyspacesClient keyClient, String
keyspaceName) {
       try {
           DeleteKeyspaceRequest deleteKeyspaceRequest =
DeleteKeyspaceRequest.builder()
                   .keyspaceName(keyspaceName)
                   .build();

           keyClient.deleteKeyspace(deleteKeyspaceRequest);

       } catch (KeyspacesException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see DeleteKeyspace in *AWS SDK for Java 2.x API Reference*.

`DeleteTable`

The following code example shows how to use `DeleteTable`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   public static void deleteTable(KeyspacesClient keyClient, String keyspaceName,
String tableName) {
       try {
           DeleteTableRequest tableRequest = DeleteTableRequest.builder()
                   .keyspaceName(keyspaceName)
                   .tableName(tableName)
                   .build();

           keyClient.deleteTable(tableRequest);

       } catch (KeyspacesException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see DeleteTable in *AWS SDK for Java 2.x API Reference*.

`GetKeyspace`

The following code example shows how to use `GetKeyspace`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   public static void checkKeyspaceExistence(KeyspacesClient keyClient, String
keyspaceName) {
       try {
           GetKeyspaceRequest keyspaceRequest = GetKeyspaceRequest.builder()
                   .keyspaceName(keyspaceName)
                   .build();

           GetKeyspaceResponse response = keyClient.getKeyspace(keyspaceRequest);
           String name = response.keyspaceName();
           System.out.println("The " + name + " KeySpace is ready");
```

```
        } catch (KeyspacesException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see GetKeyspace in *AWS SDK for Java 2.x API Reference*.

`GetTable`

The following code example shows how to use `GetTable`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   public static void checkTable(KeyspacesClient keyClient, String keyspaceName,
String tableName)
            throws InterruptedException {
        try {
            boolean tableStatus = false;
            String status;
            GetTableResponse response = null;
            GetTableRequest tableRequest = GetTableRequest.builder()
                    .keyspaceName(keyspaceName)
                    .tableName(tableName)
                    .build();

            while (!tableStatus) {
                response = keyClient.getTable(tableRequest);
                status = response.statusAsString();
                System.out.println(". The table status is " + status);

                if (status.compareTo("ACTIVE") == 0) {
                    tableStatus = true;
                }
```

```
                Thread.sleep(500);
            }

            List<ColumnDefinition> cols = response.schemaDefinition().allColumns();
            for (ColumnDefinition def : cols) {
                System.out.println("The column name is " + def.name());
                System.out.println("The column type is " + def.type());
            }

        } catch (KeyspacesException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see GetTable in *AWS SDK for Java 2.x API Reference*.

`ListKeyspaces`

The following code example shows how to use `ListKeyspaces`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    public static void listKeyspacesPaginator(KeyspacesClient keyClient) {
        try {
            ListKeyspacesRequest keyspacesRequest = ListKeyspacesRequest.builder()
                    .maxResults(10)
                    .build();

            ListKeyspacesIterable listRes =
keyClient.listKeyspacesPaginator(keyspacesRequest);
            listRes.stream()
                    .flatMap(r -> r.keyspaces().stream())
                    .forEach(content -> System.out.println(" Name: " +
content.keyspaceName()));
```

```
        } catch (KeyspacesException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see ListKeyspaces in *AWS SDK for Java 2.x API Reference*.

`ListTables`

The following code example shows how to use `ListTables`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    public static void listTables(KeyspacesClient keyClient, String keyspaceName) {
        try {
            ListTablesRequest tablesRequest = ListTablesRequest.builder()
                    .keyspaceName(keyspaceName)
                    .build();

            ListTablesIterable listRes =
keyClient.listTablesPaginator(tablesRequest);
            listRes.stream()
                    .flatMap(r -> r.tables().stream())
                    .forEach(content -> System.out.println(" ARN: " +
content.resourceArn() +
                            " Table name: " + content.tableName()));

        } catch (KeyspacesException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see ListTables in *AWS SDK for Java 2.x API Reference*.

`RestoreTable`

The following code example shows how to use `RestoreTable`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   public static void restoreTable(KeyspacesClient keyClient, String keyspaceName,
ZonedDateTime utc) {
       try {
           Instant myTime = utc.toInstant();
           RestoreTableRequest restoreTableRequest = RestoreTableRequest.builder()
                   .restoreTimestamp(myTime)
                   .sourceTableName("Movie")
                   .targetKeyspaceName(keyspaceName)
                   .targetTableName("MovieRestore")
                   .sourceKeyspaceName(keyspaceName)
                   .build();

           RestoreTableResponse response =
keyClient.restoreTable(restoreTableRequest);
           System.out.println("The ARN of the restored table is " +
response.restoredTableARN());

       } catch (KeyspacesException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see RestoreTable in *AWS SDK for Java 2.x API Reference*.

`UpdateTable`

The following code example shows how to use `UpdateTable`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   public static void updateTable(KeyspacesClient keyClient, String keySpace,
String tableName) {
       try {
           ColumnDefinition def = ColumnDefinition.builder()
                   .name("watched")
                   .type("boolean")
                   .build();

           UpdateTableRequest tableRequest = UpdateTableRequest.builder()
                   .keyspaceName(keySpace)
                   .tableName(tableName)
                   .addColumns(def)
                   .build();

           keyClient.updateTable(tableRequest);

       } catch (KeyspacesException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see UpdateTable in *AWS SDK for Java 2.x API Reference*.

Kinesis examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Kinesis.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions
- Serverless examples

Actions

`CreateStream`

The following code example shows how to use `CreateStream`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.kinesis.KinesisClient;
import software.amazon.awssdk.services.kinesis.model.CreateStreamRequest;
import software.amazon.awssdk.services.kinesis.model.KinesisException;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class CreateDataStream {
    public static void main(String[] args) {
```

```
        final String usage = """

                Usage:
                    <streamName>

                Where:
                    streamName - The Amazon Kinesis data stream (for example,
 StockTradeStream).
                """;

        if (args.length != 1) {
            System.out.println(usage);
            System.exit(1);
        }

        String streamName = args[0];
        Region region = Region.US_EAST_1;
        KinesisClient kinesisClient = KinesisClient.builder()
                .region(region)
                .build();
        createStream(kinesisClient, streamName);
        System.out.println("Done");
        kinesisClient.close();
    }

    public static void createStream(KinesisClient kinesisClient, String streamName)
 {
        try {
            CreateStreamRequest streamReq = CreateStreamRequest.builder()
                    .streamName(streamName)
                    .shardCount(1)
                    .build();

            kinesisClient.createStream(streamReq);

        } catch (KinesisException e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
    }
}
```

- For API details, see CreateStream in *AWS SDK for Java 2.x API Reference*.

`DeleteStream`

The following code example shows how to use `DeleteStream`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import software.amazon.awssdk.regions.Region;

Serverless examples

Invoke a Lambda function from a Kinesis trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from a Kinesis stream. The function retrieves the Kinesis payload, decodes from Base64, and logs the record contents.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming a Kinesis event with Lambda using Java.

```
// Copyright Amazon.com, Inc. or its affiliates. All Rights Reserved.
// SPDX-License-Identifier: Apache-2.0
package example;

import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.LambdaLogger;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.KinesisEvent;

public class Handler implements RequestHandler<KinesisEvent, Void> {
    @Override
    public Void handleRequest(final KinesisEvent event, final Context context) {
        LambdaLogger logger = context.getLogger();
        if (event.getRecords().isEmpty()) {
            logger.log("Empty Kinesis Event received");
            return null;
        }
        for (KinesisEvent.KinesisEventRecord record : event.getRecords()) {
            try {
                logger.log("Processed Event with EventId: "+record.getEventID());
                String data = new String(record.getKinesis().getData().array());
                logger.log("Data:"+ data);
                // TODO: Do interesting work based on the new data
            }
            catch (Exception ex) {
                logger.log("An error occurred:"+ex.getMessage());
                throw ex;
            }
        }
        logger.log("Successfully processed:"+event.getRecords().size()+" records");
        return null;
    }
```

```
}
```

Reporting batch item failures for Lambda functions with a Kinesis trigger

The following code example shows how to implement partial batch response for Lambda functions that receive events from a Kinesis stream. The function reports the batch item failures in the response, signaling to Lambda to retry those messages later.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Reporting Kinesis batch item failures with Lambda using Java.

```

import java.io.Serializable;
import java.util.ArrayList;
import java.util.List;

public class ProcessKinesisRecords implements RequestHandler<KinesisEvent,
 StreamsEventResponse> {

    @Override
    public StreamsEventResponse handleRequest(KinesisEvent input, Context context) {

        List<StreamsEventResponse.BatchItemFailure> batchItemFailures = new
 ArrayList<>();
        String curRecordSequenceNumber = "";
```

```
        for (KinesisEvent.KinesisEventRecord kinesisEventRecord :
 input.getRecords()) {
            try {
                //Process your record
                KinesisEvent.Record kinesisRecord = kinesisEventRecord.getKinesis();
                curRecordSequenceNumber = kinesisRecord.getSequenceNumber();

            } catch (Exception e) {
                /* Since we are working with streams, we can return the failed item
 immediately.
                   Lambda will immediately begin to retry processing from this
 failed item onwards. */
                batchItemFailures.add(new
 StreamsEventResponse.BatchItemFailure(curRecordSequenceNumber));
                return new StreamsEventResponse(batchItemFailures);
            }
        }

       return new StreamsEventResponse(batchItemFailures);
    }
}
```

AWS KMS examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with AWS KMS.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello AWS Key Management Service

The following code examples show how to get started using AWS Key Management Service.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import software.amazon.awssdk.services.kms.KmsAsyncClient;
import software.amazon.awssdk.services.kms.model.ListKeysRequest;
import software.amazon.awssdk.services.kms.paginators.ListKeysPublisher;
import java.util.concurrent.CompletableFuture;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class HelloKMS {
    public static void main(String[] args) {
        listAllKeys();
    }

    public static void listAllKeys() {
        KmsAsyncClient kmsAsyncClient = KmsAsyncClient.builder()
            .build();
        ListKeysRequest listKeysRequest = ListKeysRequest.builder()
            .limit(15)
            .build();

        /*
         * The `subscribe` method is required when using paginator methods in the
 AWS SDK
         * because paginator methods return an instance of a `ListKeysPublisher`,
 which is
         * based on a reactive stream. This allows asynchronous retrieval of
 paginated
         * results as they become available. By subscribing to the stream, we can
 process
```

```
         * each page of results as they are emitted.
         */
        ListKeysPublisher keysPublisher =
 kmsAsyncClient.listKeysPaginator(listKeysRequest);
        CompletableFuture<Void> future = keysPublisher
            .subscribe(r -> r.keys().forEach(key ->
                System.out.println("The key ARN is: " + key.keyArn() + ". The key Id
 is: " + key.keyId())))
            .whenComplete((result, exception) -> {
                if (exception != null) {
                    System.err.println("Error occurred: " + exception.getMessage());
                } else {
                    System.out.println("Successfully listed all keys.");
                }
            });

        try {
            future.join();
        } catch (Exception e) {
            System.err.println("Failed to list keys: " + e.getMessage());
        }
    }
}
```

- For API details, see ListKeys in *AWS SDK for Java 2.x API Reference*.

Topics

- Basics
- Actions

Basics

Learn the basics

The following code example shows how to:

- Create a KMS key.
- List KMS keys for your account and get details about them.
- Enable and disable KMS keys.

- Generate a symmetric data key that can be used for client-side encryption.
- Generate an asymmetric key used to digitally sign data.
- Tag keys.
- Delete KMS keys.

SDK for Java 2.x

            A key policy is a resource policy for a KMS key. Key policies are the
primary way to control
            access to KMS keys. Every KMS key must have exactly one key policy. The
statements in the key policy
            determine who has permission to use the KMS key and how they can use
it.
            You can also use IAM policies and grants to control access to the KMS
key, but every KMS key
            must have a key policy.

            By default, when you create a key by using the SDK, a policy is created
that
            gives the AWS account that owns the KMS key full access to the KMS key.

            Let's try to replace the automatically created policy with the following
policy.

                "Version": "2012-10-17",

           });
   }
```

- For API details, see DeleteAlias in *AWS SDK for Java 2.x API Reference*.

`DescribeKey`

The following code example shows how to use `DescribeKey`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   /**
    * Asynchronously checks if a specified key is enabled.
    *
    * @param keyId the ID of the key to check
    * @return a {@link CompletableFuture} that, when completed, indicates whether
the key is enabled or not
```

```
     *
     * @throws RuntimeException if an exception occurs while checking the key state
     */
    public CompletableFuture<Boolean> isKeyEnabledAsync(String keyId) {
        DescribeKeyRequest keyRequest = DescribeKeyRequest.builder()
            .keyId(keyId)
            .build();

        CompletableFuture<DescribeKeyResponse> responseFuture =
getAsyncClient().describeKey(keyRequest);
        return responseFuture.whenComplete((resp, ex) -> {
            if (resp != null) {
                KeyState keyState = resp.keyMetadata().keyState();
                if (keyState == KeyState.ENABLED) {
                    logger.info("The key is enabled.");
                } else {
                    logger.info("The key is not enabled. Key state: {}", keyState);
                }
            } else {
                throw new RuntimeException(ex);
            }
        }).thenApply(resp -> resp.keyMetadata().keyState() == KeyState.ENABLED);
    }
```

- For API details, see DescribeKey in *AWS SDK for Java 2.x API Reference*.

`DisableKey`

The following code example shows how to use `DisableKey`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /**
     * Asynchronously disables the specified AWS Key Management Service (KMS) key.
     *
```

```
    * @param keyId the ID or Amazon Resource Name (ARN) of the KMS key to be
disabled
    * @return a CompletableFuture that, when completed, indicates that the key has
been disabled successfully
    */

Lambda examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Lambda.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

AWS community contributions are examples that were created and are maintained by multiple teams across AWS. To provide feedback, use the mechanism provided in the linked repositories.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Lambda

The following code examples show how to get started using Lambda.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /**
     * Lists the AWS Lambda functions associated with the current AWS account.
     *
     * @param awsLambda an instance of the {@link LambdaClient} class, which is used
to interact with the AWS Lambda service
     *
     * @throws LambdaException if an error occurs while interacting with the AWS
Lambda service
     */
    public static void listFunctions(LambdaClient awsLambda) {
        try {
            ListFunctionsResponse functionResult = awsLambda.listFunctions();
            List<FunctionConfiguration> list = functionResult.functions();
            for (FunctionConfiguration config : list) {
                System.out.println("The function name is " + config.functionName());
            }

        } catch (LambdaException e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
    }
```

- For API details, see ListFunctions in *AWS SDK for Java 2.x API Reference*.

- AWS community contributions

Basics

Learn the basics

The following code example shows how to:

- Create an IAM role and Lambda function, then upload handler code.
- Invoke the function with a single parameter and get results.
- Update the function code and configure with an environment variable.
- Invoke the function with new parameters and get results. Display the returned execution log.
- List the functions for your account, then clean up resources.

For more information, see Create a Lambda function with the console.

SDK for Java 2.x

```
/*
 *  Lambda function names appear as:
 *
 *  arn:aws:lambda:us-west-2:335556666777:function:HelloFunction
 *
 *  To find this value, look at the function in the AWS Management Console.
 *
 *  Before running this Java code example, set up your development environment,
including your credentials.
 *
 *  For more information, see this documentation topic:
 *
 *  https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 *  This example performs the following tasks:
```

```
 *
 * 1. Creates an AWS Lambda function.
 * 2. Gets a specific AWS Lambda function.
 * 3. Lists all Lambda functions.
 * 4. Invokes a Lambda function.
 * 5. Updates the Lambda function code and invokes it again.
 * 6. Updates a Lambda function's configuration value.
 * 7. Deletes a Lambda function.
 */

used to interact with the AWS Lambda service
    * @param functionName the name of the AWS Lambda function to retrieve
information about
    */
```

```
    public static void getFunction(LambdaClient awsLambda, String functionName) {
        try {
            GetFunctionRequest functionRequest = GetFunctionRequest.builder()
                .functionName(functionName)
                .build();

            GetFunctionResponse response = awsLambda.getFunction(functionRequest);
            System.out.println("The runtime of this Lambda function is " +
response.configuration().runtime());

        } catch (LambdaException e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
    }
```

- For API details, see GetFunction in *AWS SDK for Java 2.x API Reference*.

`Invoke`

The following code example shows how to use `Invoke`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /**
     * Invokes a specific AWS Lambda function.
     *
     * @param awsLambda    an instance of {@link LambdaClient} to interact with the
AWS Lambda service
     * @param functionName the name of the AWS Lambda function to be invoked
     */
    public static void invokeFunction(LambdaClient awsLambda, String functionName) {
        InvokeResponse res;
        try {
```

```
            // Need a SdkBytes instance for the payload.
            JSONObject jsonObj = new JSONObject();
            jsonObj.put("inputValue", "2000");
            String json = jsonObj.toString();
            SdkBytes payload = SdkBytes.fromUtf8String(json);

            InvokeRequest request = InvokeRequest.builder()
                .functionName(functionName)
                .payload(payload)
                .build();

            res = awsLambda.invoke(request);
            String value = res.payload().asUtf8String();
            System.out.println(value);

        } catch (LambdaException e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
    }
```

- For API details, see Invoke in *AWS SDK for Java 2.x API Reference*.

`UpdateFunctionCode`

The following code example shows how to use `UpdateFunctionCode`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    /**
     * Updates the code for an AWS Lambda function.
     *
     * @param awsLambda  the AWS Lambda client
     * @param functionName the name of the Lambda function to update
```

```
    * @param bucketName the name of the S3 bucket where the function code is
located
    * @param key the key (file name) of the function code in the S3 bucket
    * @throws LambdaException if there is an error updating the function code
    */
   public static void updateFunctionCode(LambdaClient awsLambda, String
functionName, String bucketName, String key) {
       try {
           LambdaWaiter waiter = awsLambda.waiter();
           UpdateFunctionCodeRequest functionCodeRequest =
UpdateFunctionCodeRequest.builder()
                .functionName(functionName)
                .publish(true)
                .s3Bucket(bucketName)
                .s3Key(key)
                .build();

           UpdateFunctionCodeResponse response =
awsLambda.updateFunctionCode(functionCodeRequest);
           GetFunctionConfigurationRequest getFunctionConfigRequest =
GetFunctionConfigurationRequest.builder()
                .functionName(functionName)
                .build();

           WaiterResponse<GetFunctionConfigurationResponse> waiterResponse = waiter
                .waitUntilFunctionUpdated(getFunctionConfigRequest);
           waiterResponse.matched().response().ifPresent(System.out::println);
           System.out.println("The last modified value is " +
response.lastModified());

       } catch (LambdaException e) {
           System.err.println(e.getMessage());
           System.exit(1);
       }
   }
```

- For API details, see UpdateFunctionCode in *AWS SDK for Java 2.x API Reference*.

`UpdateFunctionConfiguration`

The following code example shows how to use `UpdateFunctionConfiguration`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   /**
    * Updates the configuration of an AWS Lambda function.
    *
    * @param awsLambda     the {@link LambdaClient} instance to use for the AWS
Lambda operation
    * @param functionName  the name of the AWS Lambda function to update
    * @param handler       the new handler for the AWS Lambda function
    *
    * @throws LambdaException if there is an error while updating the function
configuration
    */
   public static void updateFunctionConfiguration(LambdaClient awsLambda, String
functionName, String handler) {
       try {
           UpdateFunctionConfigurationRequest configurationRequest =
UpdateFunctionConfigurationRequest.builder()
               .functionName(functionName)
               .handler(handler)
               .runtime(Runtime.JAVA17)
               .build();

           awsLambda.updateFunctionConfiguration(configurationRequest);

       } catch (LambdaException e) {
           System.err.println(e.getMessage());
           System.exit(1);
       }
   }
```

- For API details, see UpdateFunctionConfiguration in *AWS SDK for Java 2.x API Reference*.

Scenarios

Create a serverless application to manage photos

The following code example shows how to create a serverless application that lets users manage photos using labels.

SDK for Java 2.x

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

For a deep dive into the origin of this example see the post on AWS Community.

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

Create an application to analyze customer feedback

The following code example shows how to create an application that analyzes customer comment cards, translates them from their original language, determines their sentiment, and generates an audio file from the translated text.

SDK for Java 2.x

This example application analyzes and stores customer feedback cards. Specifically, it fulfills the need of a fictitious hotel in New York City. The hotel receives feedback from guests in various languages in the form of physical comment cards. That feedback is uploaded into the app through a web client. After an image of a comment card is uploaded, the following steps occur:

- Text is extracted from the image using Amazon Textract.
- Amazon Comprehend determines the sentiment of the extracted text and its language.
- The extracted text is translated to English using Amazon Translate.
- Amazon Polly synthesizes an audio file from the extracted text.

The full app can be deployed with the AWS CDK. For source code and deployment instructions, see the project in GitHub.

Services used in this example

- Amazon Comprehend
- Lambda
- Amazon Polly
- Amazon Textract
- Amazon Translate

Use API Gateway to invoke a Lambda function

The following code example shows how to create an AWS Lambda function invoked by Amazon API Gateway.

SDK for Java 2.x

Shows how to create an AWS Lambda function by using the Lambda Java runtime API.
This example invokes different AWS services to perform a specific use case. This example demonstrates how to create a Lambda function invoked by Amazon API Gateway that scans an Amazon DynamoDB table for work anniversaries and uses Amazon Simple Notification Service (Amazon SNS) to send a text message to your employees that congratulates them at their one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- DynamoDB

- Lambda
- Amazon SNS

Use Step Functions to invoke Lambda functions

The following code example shows how to create an AWS Step Functions state machine that invokes AWS Lambda functions in sequence.

SDK for Java 2.x

Shows how to create an AWS serverless workflow by using AWS Step Functions and the AWS SDK for Java 2.x. Each workflow step is implemented using an AWS Lambda function.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- DynamoDB
- Lambda
- Amazon SES
- Step Functions

Use scheduled events to invoke a Lambda function

The following code example shows how to create an AWS Lambda function invoked by an Amazon EventBridge scheduled event.

SDK for Java 2.x

Shows how to create an Amazon EventBridge scheduled event that invokes an AWS Lambda function. Configure EventBridge to use a cron expression to schedule when the Lambda function is invoked. In this example, you create a Lambda function by using the Lambda Java runtime API. This example invokes different AWS services to perform a specific use case. This example demonstrates how to create an app that sends a mobile text message to your employees that congratulates them at the one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- CloudWatch Logs
- DynamoDB
- EventBridge
- Lambda
- Amazon SNS

Use the Neptune API to query graph data

The following code example shows how to use the Neptune API to query graph data.

SDK for Java 2.x

Shows how to use Amazon Neptune Java API to create a Lambda function that queries graph data within the VPC.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Lambda
- Neptune

Serverless examples

Connecting to an Amazon RDS database in a Lambda function

The following code example shows how to implement a Lambda function that connects to an RDS database. The function makes a simple database request and returns the result.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Connecting to an Amazon RDS database in a Lambda function using Java.

```
import com.amazonaws.services.lambda.runtime.Context;

 event.get("events");
        for (Map<String, Object> record : events) {
```

```
            Map<String, Object> eventData = (Map<String, Object>)
 record.get("event");
            processEventData(eventData);
        }

        return "OK";
    }

    @SuppressWarnings("unchecked")
    private void processEventData(Map<String, Object> eventData) {
        String operationType = (String) eventData.get("operationType");
        System.out.println("operationType: %s".formatted(operationType));

        Map<String, Object> ns = (Map<String, Object>) eventData.get("ns");

        String db = (String) ns.get("db");
        System.out.println("db: %s".formatted(db));
        String coll = (String) ns.get("coll");
        System.out.println("coll: %s".formatted(coll));

        Map<String, Object> fullDocument = (Map<String, Object>)
 eventData.get("fullDocument");
        System.out.println("fullDocument: %s".formatted(fullDocument));
    }

}
```

Invoke a Lambda function from an Amazon MSK trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from an Amazon MSK cluster. The function retrieves the MSK payload and logs the record contents.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming an Amazon MSK event with Lambda using Java.

```
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.KafkaEvent;
import com.amazonaws.services.lambda.runtime.events.KafkaEvent.KafkaEventRecord;

import java.util.Base64;
import java.util.Map;

public class Example implements RequestHandler<KafkaEvent, Void> {

    @Override
    public Void handleRequest(KafkaEvent event, Context context) {
        for (Map.Entry<String, java.util.List<KafkaEventRecord>> entry :
 event.getRecords().entrySet()) {
            String key = entry.getKey();
            System.out.println("Key: " + key);

            for (KafkaEventRecord record : entry.getValue()) {
                System.out.println("Record: " + record);

                byte[] value = Base64.getDecoder().decode(record.getValue());
                String message = new String(value);
                System.out.println("Message: " + message);
            }
        }

        return null;
    }
}
```

Invoke a Lambda function from an Amazon S3 trigger

The following code example shows how to implement a Lambda function that receives an event triggered by uploading an object to an S3 bucket. The function retrieves the S3 bucket name and object key from the event parameter and calls the Amazon S3 API to retrieve and log the content type of the object.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

}
```

Invoke a Lambda function from an Amazon SQS trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving messages from an SQS queue. The function retrieves the messages from the event parameter and logs the content of each message.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming an SQS event with Lambda using Java.

Build and test a serverless application

The following code example shows how to build and test a serverless application using API Gateway with Lambda and DynamoDB

SDK for Java 2.x

Shows how to build and test a serverless application that consists of an API Gateway with Lambda and DynamoDB using the Java SDK.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- DynamoDB
- Lambda

Amazon Lex examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Lex.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Scenarios

Scenarios

Building an Amazon Lex chatbot

The following code example shows how to create a chatbot to engage your website visitors.

SDK for Java 2.x

Shows how to use the Amazon Lex API to create a Chatbot within a web application to engage your web site visitors.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Amazon Comprehend
- Amazon Lex
- Amazon Translate

Amazon Location examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Location.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon Location Service

The following code examples show how to get started using Amazon Location Service.

Basics

Learn the basics

The following code example shows how to:

- Create an Amazon Location map.
- Create an Amazon Location API key.
- Display Map URL.
- Create a geofence collection.
- Store a geofence geometry.
- Create a tracker resource.
- Update the position of a device.
- Retrieve the most recent position update for a specified device.

- Create a route calculator.
- Determine the distance between Seattle and Vancouver.
- Use Amazon Location higher level APIs.
- Delete the Amazon Location Assets.

            AWS Location Service is a fully managed service offered by Amazon Web
Services (AWS) that
            provides location-based services for developers. This service simplifies
            the integration of location-based features into applications, making it
            easier to build and deploy location-aware applications.

            The AWS Location Service offers a range of location-based services,
            including:

            Maps: The service provides access to high-quality maps, satellite
imagery,\s
            and geospatial data from various providers, allowing developers to\s
            easily embed maps into their applications.

            Tracking: The Location Service enables real-time tracking of mobile
devices,\s
            assets, or other entities, allowing developers to build applications\s
            that can monitor the location of people, vehicles, or other objects.
```

```
            Geocoding: The service provides the ability to convert addresses or\s
            location names into geographic coordinates (latitude and longitude),\s
            and vice versa, enabling developers to integrate location-based search\s
            and routing functionality into their applications.

        logger.info("""
            An AWS Location geofence is a virtual boundary that defines a geographic
area
            on a map. It is a useful feature for tracking the location of
            assets or monitoring the movement of objects within a specific region.

            To define a geofence, you need to specify the coordinates of a
            polygon that represents the area of interest. The polygon must be
            defined in a counter-clockwise direction, meaning that the points of
            the polygon must be listed in a counter-clockwise order.

            This is a requirement for the AWS Location service to correctly
            interpret the geofence and ensure that the location data is
            accurately processed within the defined area.
            """);

Location Service Places examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Location Service Places.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

- For API details, see StartChangeSet in *AWS SDK for Java 2.x API Reference*.

Create a public or limited AMI product and public offer with hourly monthly pricing

The following code example shows how to create a public or limited AMI product and public offer with hourly monthly pricing. This example creates either a standard or custom EULA.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to RunChangesets in *Utilities to start a changeset* from the **Utilities** section.

```

Create a public or limited AMI product and public offer with hourly pricing

The following code example shows how to create a public or limited AMI product and public offer with hourly pricing. This example creates either and standard or custom EULA.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to `RunChangesets` in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
    "ChangeSet": [
        {

Publish multi-use resale authorization with an expiration date and a EULA

The following code example shows how to publish multi-use resale authorization with an expiration date for any product type and add a custom EULA to be sent to the buyer.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to `RunChangesets` in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
    "ChangeSet": [
        {
            "ChangeType": "CreateResaleAuthorization",
            "ChangeName": "ResaleAuthorization",

Publish multi-use resale authorization without an expiration date

The following code example shows how to publish multi-use resale authorization without an expiration date for an AMI product with hourly annual pricing so a CP can use that to create a CPPO.

SDK for Java 2.x

Restrict resale authorization

The following code example shows how to restrict resale authorization.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to RunChangesets in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
    "ChangeSet": [
        {
            "ChangeType": "RestrictResaleAuthorization",
            "Entity": {
                "Type": "ResaleAuthorization@1.0",
                "Identifier": "resaleauthz-1111111111111"
            },
            "DetailsDocument": {}
        }
    ]
}
```

- For API details, see StartChangeSet in *AWS SDK for Java 2.x API Reference*.

Update name and description of one-time or multi-use resale authorization

The following code example shows how to update name and description of one-time or multi-use resale authorization before publishing for any product type.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to RunChangesets in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
    "ChangeSet": [
        {
            "ChangeType":"UpdateInformation",
            "Entity": {
             "Type": "ResaleAuthorization@1.0",
             "Identifier": "resaleauthz-1111111111111"
            },
            "DetailsDocument": {
             "Name": "TestResaleAuthorization",
                "Description": "Worldwide ResaleAuthorization for Test Product"
            }
        }
    ]
}
```

- For API details, see StartChangeSet in *AWS SDK for Java 2.x API Reference*.

SaaS products

Create a draft SaaS product with a draft public offer

The following code example shows how to create a draft SaaS product with a draft public offer.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to RunChangesets in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog":"AWSMarketplace",
```

```
    "ChangeSet": [
        {
            "ChangeType": "CreateProduct",
            "ChangeName": "CreateProductChange",
            "Entity": {
                "Type": "SaaSProduct@1.0"
            },
            "DetailsDocument": {
              "ProductTitle": "Sample product"
            }
        },
        {
            "ChangeType": "CreateOffer",
            "ChangeName": "CreateOfferChange",
            "Entity": {
                "Type": "Offer@1.0"
            },
            "DetailsDocument": {
                "ProductId": "$CreateProductChange.Entity.Identifier",
                "Name": "Test Offer"
            }
        }
    ]
}
```

- For API details, see StartChangeSet in *AWS SDK for Java 2.x API Reference*.

Create a public or limited SaaS product and public offer with contract pricing

The following code example shows how to create a public or limited SaaS product and public offer with contract pricing. This example creates either a standard or custom EULA.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to `RunChangesets` in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
    "ChangeSet": [
        {
            "ChangeType": "CreateProduct",

Create a public or limited SaaS product and public offer with contract with Pay-As-You-Go pricing

The following code example shows how to create a public or limited SaaS product and public offer with a contract with Pay-As-You-Go pricing. This example creates either a standard or custom EULA.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to `RunChangesets` in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
    "ChangeSet": [
        {

Publish a SaaS product and associated public offer from an existing draft

The following code example shows how to publish a SaaS product and associated public offer from an existing draft. The product will be in a limited state by default.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Marketplace API Reference Code Library repository.

```
{
    "Catalog":"AWSMarketplace",
    "ChangeSet": [
        {
            "ChangeType": "UpdateVisibility",
            "ChangeName": "CreateProductChange",
            "Entity": {
                "Type": "SaaSProduct@1.0",
                "Identifier": "prod-1111111111111"
            },
            "DetailsDocument": {
                "TargetVisibility": "Public"
```

```
            }
        }
    ]
}
```

- For API details, see StartChangeSet in *AWS SDK for Java 2.x API Reference*.

Update dimensions on an AMI or SaaS product

The following code example shows how to update dimensions on an AMI or SaaS product.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Marketplace API Reference Code Library repository.

To run this example, pass the following JSON changeset to RunChangesets in *Utilities to start a changeset* from the **Utilities** section.

```
{
    "Catalog": "AWSMarketplace",
    "ChangeSet": [
        {
            "ChangeType": "UpdateDimensions",
            "Entity": {
                "Type": "SaaSProduct@1.0",
                "Identifier": "prod-111111111111"
            },
            "DetailsDocument": [
                {
                    "Key": "BasicService",
                    "Types": [
                        "Entitled"
                    ],
                    "Name": "Some new name",
                    "Description": "Some new description"
                }
            ]
```

```
        }
    ]
}
```

- For API details, see StartChangeSet in *AWS SDK for Java 2.x API Reference*.

Utilities

Utilities to start a changeset

The following code example shows how to define utilities to start a changeset.

SDK for Java 2.x

MediaConvert examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with MediaConvert.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`CreateJob`

The following code example shows how to use `CreateJob`.

SDK for Java 2.x

Migration Hub examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Migration Hub.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Actions

Actions

`DeleteProgressUpdateStream`

The following code example shows how to use `DeleteProgressUpdateStream`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.migrationhub.MigrationHubClient;
import
 software.amazon.awssdk.services.migrationhub.model.DeleteProgressUpdateStreamRequest;
import software.amazon.awssdk.services.migrationhub.model.MigrationHubException;

/**

Amazon MSK examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon MSK.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

- Serverless examples

Serverless examples

Invoke a Lambda function from an Amazon MSK trigger

The following code example shows how to implement a Lambda function that receives an event triggered by receiving records from an Amazon MSK cluster. The function retrieves the MSK payload and logs the record contents.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Serverless examples repository.

Consuming an Amazon MSK event with Lambda using Java.

```
import com.amazonaws.services.lambda.runtime.Context;
import com.amazonaws.services.lambda.runtime.RequestHandler;
import com.amazonaws.services.lambda.runtime.events.KafkaEvent;
import com.amazonaws.services.lambda.runtime.events.KafkaEvent.KafkaEventRecord;

import java.util.Base64;
import java.util.Map;

public class Example implements RequestHandler<KafkaEvent, Void> {

    @Override
    public Void handleRequest(KafkaEvent event, Context context) {
        for (Map.Entry<String, java.util.List<KafkaEventRecord>> entry :
 event.getRecords().entrySet()) {
            String key = entry.getKey();
            System.out.println("Key: " + key);

            for (KafkaEventRecord record : entry.getValue()) {
                System.out.println("Record: " + record);

                byte[] value = Base64.getDecoder().decode(record.getValue());
                String message = new String(value);
                System.out.println("Message: " + message);
```

```
            }
        }

        return null;
    }
}
```

Neptune examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Neptune.

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Get started

Hello Amazon Neptune

The following code examples show how to get started using Neptune.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
```

```
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 */
public class HelloNeptune {
    public static void main(String[] args) {
        NeptuneAsyncClient neptuneClient = NeptuneAsyncClient.create();
        describeDbCluster(neptuneClient).join(); // This ensures the async code runs
 to completion
    }

    /**
     * Describes the Amazon Neptune DB clusters.
     *
     * @param neptuneClient the Neptune asynchronous client used to make the request
     * @return a {@link CompletableFuture} that completes when the operation is
 finished
     */
    public static CompletableFuture<Void> describeDbCluster(NeptuneAsyncClient
 neptuneClient) {
        DescribeDbClustersRequest request = DescribeDbClustersRequest.builder()
                .maxRecords(20)
                .build();

        SdkPublisher<DescribeDbClustersResponse> paginator =
 neptuneClient.describeDBClustersPaginator(request);
        CompletableFuture<Void> future = new CompletableFuture<>();

        paginator.subscribe(new Subscriber<DescribeDbClustersResponse>() {
            private Subscription subscription;

            @Override
            public void onSubscribe(Subscription s) {
                this.subscription = s;
                s.request(Long.MAX_VALUE); // request all items
            }

            @Override
            public void onNext(DescribeDbClustersResponse response) {
                response.dbClusters().forEach(cluster -> {
                    System.out.println("Cluster Identifier: " +
 cluster.dbClusterIdentifier());
                    System.out.println("Status: " + cluster.status());
```

```
                });
            }

            @Override
            public void onError(Throwable t) {
                future.completeExceptionally(t);
            }

            @Override
            public void onComplete() {
                future.complete(null);
            }
        });

        return future.whenComplete((result, throwable) -> {
            neptuneClient.close();
            if (throwable != null) {
                System.err.println("Error describing DB clusters: " +
throwable.getMessage());
            }
        });
    }
```

Topics

- Basics
- Actions
- Scenarios

Basics

Learn the basics

The following code example shows how to:

- Create an Amazon Neptune Subnet Group.
- Create an Neptune Cluster.
- Create an Neptune Instance.

- Check the status of the Neptune Instance.
- Show Neptune cluster details.
- Stop the Neptune cluster.
- Start the Neptune cluster.
- Delete the Neptune Assets.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run an interactive scenario demonstrating Neptune features.

```
public class NeptuneScenario {
    public static final String DASHES = new String(new char[80]).replace("\0", "-");
    private static final Logger logger =
 LoggerFactory.getLogger(NeptuneScenario.class);
    static Scanner scanner = new Scanner(System.in);
    static NeptuneActions neptuneActions = new NeptuneActions();

    public static void main(String[] args) {
        final String usage =
                """
                Usage:
                    <subnetGroupName> <clusterName> <dbInstanceId>

                Where:
                    subnetGroupName - The name of an existing Neptune DB subnet
 group that includes subnets in at least two Availability Zones.
                    clusterName     - The unique identifier for the Neptune DB
 cluster.
                    dbInstanceId    - The identifier for a specific Neptune DB
 instance within the cluster.
                """;
        String subnetGroupName = "neptuneSubnetGroup65";
        String clusterName = "neptuneCluster65";
        String dbInstanceId = "neptuneDB65";
```

```
        logger.info("""
                   Amazon Neptune is a fully managed graph
                   database service by AWS, designed specifically
                   for handling complex relationships and connected
                   datasets at scale. It supports two popular graph models:
                   property graphs (via openCypher and Gremlin) and RDF
                   graphs (via SPARQL). This makes Neptune ideal for
                   use cases such as knowledge graphs, fraud detection,
                   social networking, recommendation engines, and
                   network management, where relationships between
                   entities are central to the data.

                   Being fully managed, Neptune handles database
                   provisioning, patching, backups, and replication,
                   while also offering high availability and durability
                   within AWS's infrastructure.

                   For developers, programming with Neptune allows
                   for building intelligent, relationship-aware
                   applications that go beyond traditional tabular
                   databases. Developers can use the AWS SDK for Java
                   to automate infrastructure operations (via NeptuneClient).

                    }
                });
    }
```

- For API details, see StopDBCluster in *AWS SDK for Java 2.x API Reference*.

Scenarios

Use the Neptune API to query graph data

The following code example shows how to use the Neptune API to query graph data.

SDK for Java 2.x

Shows how to use Amazon Neptune Java API to create a Lambda function that queries graph data within the VPC.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Lambda

- Neptune

Partner Central examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Partner Central.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other AWS services.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

Amazon Personalize examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Personalize.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

            DescribeRecipeRequest recipeRequest = DescribeRecipeRequest.builder()
                    .recipeArn(recipeArn)
                    .build();

            DescribeRecipeResponse recipeResponse =
personalizeClient.describeRecipe(recipeRequest);
            System.out.println("The recipe name is " +
recipeResponse.recipe().name());

        } catch (PersonalizeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
```

```
            System.exit(1);
        }
    }
```

- For API details, see DescribeRecipe in *AWS SDK for Java 2.x API Reference*.

`DescribeSolution`

The following code example shows how to use `DescribeSolution`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   public static void describeSpecificSolution(PersonalizeClient personalizeClient,
String solutionArn) {

        try {
            DescribeSolutionRequest solutionRequest =
DescribeSolutionRequest.builder()
                    .solutionArn(solutionArn)
                    .build();

            DescribeSolutionResponse response =
personalizeClient.describeSolution(solutionRequest);
            System.out.println("The Solution name is " +
response.solution().name());

        } catch (PersonalizeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

- For API details, see DescribeSolution in *AWS SDK for Java 2.x API Reference*.

`ListCampaigns`

The following code example shows how to use `ListCampaigns`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   public static void listAllCampaigns(PersonalizeClient personalizeClient, String
solutionArn) {

       try {
           ListCampaignsRequest campaignsRequest = ListCampaignsRequest.builder()
                   .maxResults(10)
                   .solutionArn(solutionArn)
                   .build();

           ListCampaignsResponse response =
personalizeClient.listCampaigns(campaignsRequest);
           List<CampaignSummary> campaigns = response.campaigns();
           for (CampaignSummary campaign : campaigns) {
               System.out.println("Campaign name is : " + campaign.name());
               System.out.println("Campaign ARN is : " + campaign.campaignArn());
           }

       } catch (PersonalizeException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see ListCampaigns in *AWS SDK for Java 2.x API Reference*.

`ListDatasetGroups`

The following code example shows how to use `ListDatasetGroups`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   public static void listDSGroups(PersonalizeClient personalizeClient) {

       try {
           ListDatasetGroupsRequest groupsRequest =
ListDatasetGroupsRequest.builder()
                   .maxResults(15)
                   .build();

           ListDatasetGroupsResponse groupsResponse =
personalizeClient.listDatasetGroups(groupsRequest);
           List<DatasetGroupSummary> groups = groupsResponse.datasetGroups();
           for (DatasetGroupSummary group : groups) {
               System.out.println("The DataSet name is : " + group.name());
               System.out.println("The DataSet ARN is : " +
group.datasetGroupArn());
           }

       } catch (PersonalizeException e) {
           System.err.println(e.awsErrorDetails().errorMessage());
           System.exit(1);
       }
   }
```

- For API details, see ListDatasetGroups in *AWS SDK for Java 2.x API Reference*.

`ListRecipes`

The following code example shows how to use `ListRecipes`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    public static void listAllRecipes(PersonalizeClient personalizeClient) {

       }
```

```
        return "";
    }
```

- For API details, see UpdateCampaign in *AWS SDK for Java 2.x API Reference*.

Amazon Personalize Events examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Personalize Events.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

Topics

Actions

`PutEvents`

The following code example shows how to use `PutEvents`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
    public static int putItems(PersonalizeEventsClient personalizeEventsClient,
                   String datasetArn,
                   String item1Id,
                   String item1PropertyName,
                   String item1PropertyValue,
```

```
                        String item2Id,
                        String item2PropertyName,
                        String item2PropertyValue) {

                int responseCode = 0;
                ArrayList<Item> items = new ArrayList<>();

                try {
                        Item item1 = Item.builder()
                                        .itemId(item1Id)
                                        .properties(String.format("{\"%1$s\": \"%2$s
\"}",
                                                                item1PropertyName,
 item1PropertyValue))
                                        .build();

                        items.add(item1);

                        Item item2 = Item.builder()
                                        .itemId(item2Id)
                                        .properties(String.format("{\"%1$s\": \"%2$s
\"}",
                                                                item2PropertyName,
 item2PropertyValue))
                                        .build();

                        items.add(item2);

                        PutItemsRequest putItemsRequest = PutItemsRequest.builder()
                                        .datasetArn(datasetArn)
                                        .items(items)
                                        .build();

                        responseCode =
 personalizeEventsClient.putItems(putItemsRequest).sdkHttpResponse().statusCode();
                        System.out.println("Response code: " + responseCode);
                        return responseCode;

                } catch (PersonalizeEventsException e) {
                        System.out.println(e.awsErrorDetails().errorMessage());
                }
                return responseCode;
        }
```

Amazon Personalize Runtime examples using SDK for Java 2.x

The following code examples show you how to perform actions and implement common scenarios by using the AWS SDK for Java 2.x with Amazon Personalize Runtime.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Each example includes a link to the complete source code, where you can find instructions on how to set up and run the code in context.

`GetPersonalizedRanking`

The following code example shows how to use `GetPersonalizedRanking`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```
   public static List<PredictedItem> getRankedRecs(PersonalizeRuntimeClient
personalizeRuntimeClient,
           String campaignArn,
           String userId,
           ArrayList<String> items) {

       try {
           GetPersonalizedRankingRequest rankingRecommendationsRequest =
GetPersonalizedRankingRequest.builder()
                   .campaignArn(campaignArn)
                   .userId(userId)
                   .inputList(items)
                   .build();

           GetPersonalizedRankingResponse recommendationsResponse =
personalizeRuntimeClient
                   .getPersonalizedRanking(rankingRecommendationsRequest);
           List<PredictedItem> rankedItems =
recommendationsResponse.personalizedRanking();
           int rank = 1;
           for (PredictedItem item : rankedItems) {
               System.out.println("Item ranked at position " + rank + " details");
               System.out.println("Item Id is : " + item.itemId());
               System.out.println("Item score is : " + item.score());
               System.out.println("-------------------------------------------");
               rank++;
           }
           return rankedItems;
```

```
        } catch (PersonalizeRuntimeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
        return null;
    }
```

- For API details, see GetPersonalizedRanking in *AWS SDK for Java 2.x API Reference*.

`GetRecommendations`

The following code example shows how to use `GetRecommendations`.

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Get a list of recommended items.

```
   public static void getRecs(PersonalizeRuntimeClient personalizeRuntimeClient,
String campaignArn, String userId) {

        try {
            GetRecommendationsRequest recommendationsRequest =
GetRecommendationsRequest.builder()
                    .campaignArn(campaignArn)
                    .numResults(20)
                    .userId(userId)
                    .build();

            GetRecommendationsResponse recommendationsResponse =
personalizeRuntimeClient
                    .getRecommendations(recommendationsRequest);
            List<PredictedItem> items = recommendationsResponse.itemList();
            for (PredictedItem item : items) {
                System.out.println("Item Id is : " + item.itemId());
                System.out.println("Item score is : " + item.score());
```

```
            }

        } catch (AwsServiceException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

Get a list of recommended items from a recommender created in a domain dataset group.

```
    public static void getRecs(PersonalizeRuntimeClient personalizeRuntimeClient,
String recommenderArn,
            String userId) {

        try {
            GetRecommendationsRequest recommendationsRequest =
GetRecommendationsRequest.builder()
                    .recommenderArn(recommenderArn)
                    .numResults(20)
                    .userId(userId)
                    .build();

            GetRecommendationsResponse recommendationsResponse =
personalizeRuntimeClient
                    .getRecommendations(recommendationsRequest);
            List<PredictedItem> items = recommendationsResponse.itemList();

            for (PredictedItem item : items) {
                System.out.println("Item Id is : " + item.itemId());
                System.out.println("Item score is : " + item.score());
            }
        } catch (AwsServiceException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```

Use a filter when requesting recommendations.

```
    public static void getFilteredRecs(PersonalizeRuntimeClient
personalizeRuntimeClient,
```

```
            String campaignArn,
            String userId,
            String filterArn,
            String parameter1Name,
            String parameter1Value1,
            String parameter1Value2,
            String parameter2Name,
            String parameter2Value) {

        try {

            Map<String, String> filterValues = new HashMap<>();

            filterValues.put(parameter1Name, String.format("\"%1$s\",\"%2$s\"",
                    parameter1Value1, parameter1Value2));
            filterValues.put(parameter2Name, String.format("\"%1$s\"",
                    parameter2Value));

            GetRecommendationsRequest recommendationsRequest =
GetRecommendationsRequest.builder()
                    .campaignArn(campaignArn)
                    .numResults(20)
                    .userId(userId)
                    .filterArn(filterArn)
                    .filterValues(filterValues)
                    .build();

            GetRecommendationsResponse recommendationsResponse =
personalizeRuntimeClient
                    .getRecommendations(recommendationsRequest);
            List<PredictedItem> items = recommendationsResponse.itemList();

            for (PredictedItem item : items) {
                System.out.println("Item Id is : " + item.itemId());
                System.out.println("Item score is : " + item.score());
            }
        } catch (PersonalizeRuntimeException e) {
            System.err.println(e.awsErrorDetails().errorMessage());
            System.exit(1);
        }
    }
```
